Mukerji estimates the total cost of cultivation at Rs. 160 an acre. The *Experimental Farm Reports* have investigated many important issues, such as the yield of sugar with the various races of cane, the advantages or otherwise of ratooning, and the economy of propagation by tops in place of lower portions, that is, cuttings of the mature cane. [Cf. Sen, *Rept. Agri. Stat. Dacca*, 1889, 33-7; Basu, *Agri. Lohardaga*, 1890, pt. i., 79-80; pt. ii., 37-41; Banerjee, *Agri. Cuttack*, 1893, 92-6; Voelcker, *Improv. Ind. Agri.*, 1893, 244-5; Mukerji, *Handbook Ind. Agri.*, 1901, 394-6, 398-403, 405-8; *Rept. on Cult. of Sugar by Bihar Indigo Planters*, 1901; *Admin. Rept. Beng.*, 1901-2, 24-5, etc.; Roy, *Crops of Bengal*, 1906, 100-12; Wilkie, *Sugar Cane Cultivation Bihar*, in *Agri. Journ. Ind.*, 1906, i., pt. iv., 322-8; *Repts. of Dept. Land Rec. and Agri. Beng.*; *Exper. Farm Repts. Beng.*; *Dumraon*, 1906-7, 4-10.]

. Bengal
and Assam.
Areas.

Eastern Bengal and Assa.—The area under sugar-cane for 1904-5 in Assam proper was 44,869 acres. The largest areas ordinarily occur in Sylhet, which had 20,000 acres; Sibságar, 6,925 acres; Cachar, 5,250 acres; Lakhimpur, 3,783 acres; Kámrúp, 3,688 acres; Darrang, 2,176 acres, etc. But since the separation of Bengal, 14 districts formerly treated as within that province are now returned under the new province of Eastern Bengal and Assam, and later statistics accordingly manifest an apparent provincial expansion. Thus in 1905-6 the estimated area and outturn in the new province were 201,500 acres and 188,500 tons, and in 1906-7, 199,900 acres and 193,500 tons.

The following information regarding cultivation in the Brahmaputra valley is

RATOONING

ACCHA U
OFFICINA U
Cultivation

abstracted from the account by Dr. E. Stack. A light loamy soil, with a light admixture of sand, is most suitable. It must be high land, beyond the reach of inundation. Favourite spots are the edges of a marsh or the banks of a river. The degree of manuring depends entirely upon the *raiya*'s means and inclination. Plots in the vicinity of centres of crowded population are freely manured with cow-dung and crushed mustard seed, both before and after planting with cane; on the other hand, in the more rural tracts it often receives no manure except the ashes of the grass and weeds raked out of the soil and burnt. The best cane is that raised on virgin soil or on old fallows, but land from which a crop of mustard, pulse, or summer rice (*dhu*) has been first taken is sometimes preferred. A second crop of cane, unless ratooned, is never taken, but the land is left fallow for several years. Waste or fallow land is broken up in October, then left till January or February, when ploughing starts and is continued till the middle of April. The field is then divided into strips, 8 to 12 feet wide, by drains which communicate with a ditch surrounding the field. The cane-sets are invariably the topmost joints. From the harvest season to time of planting they are kept in a cool and moist spot, placed in a half-upright position, in ground which has been turned up by the hoe, the beds of cuttings being covered with rice-straw or plantain leaves and watered if the weather be dry. The day chosen for planting out, generally about the middle of May, must be preceded by sufficient rain. In an official publication on *Seasons of Sowing and Reaping of Crops*, issued by the Reporter on Economic Products, cane is spoken of as planted from April to June. The layers are placed 2 feet apart, in trenches 3 feet distant, and these run at right angles to the drains that divide the field. After planting, a little soil, often mixed with cow-dung, is lightly scattered over them. The field is then weeded and the soil around the young shoots lightly stirred with the spade or hoe, a process which is repeated at short intervals during bright sunny weather throughout May and part of June, and at the same time manure may be applied. A few more weedings are given and the earth from the ridges is heaped about the roots of the canes in the trenches till ridge and trench are reversed. This goes on till the middle of August, after which work stops for about a month. A final weeding and earthing up is then given, in September or October, when the canes are tied together in clumps by the leaves stripped off the lower parts of the stems. Cane harvest, as a rule, does not begin till the winter rice has been reaped, that is, till after the 15th of January. The operations of cutting, crushing, boiling, etc., are carried on simultaneously from this date till the end of March, or even beginning of April. The canes are cut close to the root, the tops lopped off and reserved for layers, and the stalks, stripped of their leaves, are bound in bundles and carried to the mill. From an extensive series of crop experiments, performed from 1883 to 1902, it would appear that the yield of cane to the acre is about 10 tons and that it requires about 11.6 tons of cane to afford one ton of *gur*.

A small proportion of the annual crop is ratooned. If this is done the stripped-off leaves of the previous crop are left lying on the field till April, when they are burnt, and a month later, when the young shoots begin to appear, the crop is hoed and manure added. Such a crop is called *murha*, and is harvested earlier than the other crop, viz. in the beginning of January. [Cf. Allan, *Assam Dist. Gaz.*, 1905 (Cachar, Sylhet, Goalpara, etc.); *Crop Exper. Repts., Assam.*]

United Provinces.—On the average of the five years ending 1904–5, it is manifested that the area under sugar-cane in these provinces amounted to 49 per cent. of the total under sugar-cane in British India. In 1905–6, the area, according to the *Agricultural Statistics*, was 1,220,716 acres, viz. 954,350 in Agra, and 266,366 in Oudh. The yield was returned as 884,000 tons, though in 1904–5 it was 1,183,400 tons or, say, one ton to the acre. In Agra the acreage in 1905–6 in the most important districts was as follows:—Meerut, 108,954; Gorakhpur, 93,599; Bijnor, 77,763; Azamgarh, 69,088; Muzaffarnagar, 56,498; Basti, 55,123; Bareilly, 51,135. In Oudh:—Fyzabad, 48,157; Kheri, 41,091; Sitapur, 33,201; Barabanki, 31,691; Gonda, 27,395; Sultanpur, 22,580. The *Final Memorandum* of the Commercial Intelligence Department for 1906–7 states the area and yield for that year as 1,386,700 acres and 1,264,600 tons.

The races of cane grown in the United Provinces have already been classed, with reference to their agricultural characters and properties, into

Rotation.	three broad divisions, known as <i>ukh</i> , <i>ganná</i> and <i>paundá</i> . The methods of cultivation for the first two are the same, but differ somewhat in the case of <i>paundá</i> canes.
Irrigation.	According to Saiyid Muhammad Hadi, from whom the particulars here given have been mainly derived, the crop is grown under three different systems of treatment. "In one, the land is kept fallow for a whole year following the removal of a spring crop. In the second, a winter fallow is allowed after a rain (<i>khariif</i>) or an autumn (<i>agahni</i>) crop. In the third, the ground is prepared and cane sown immediately after a spring crop has been cleared from the land." The second system is that most commonly pursued, especially in canal-irrigated areas.
Seasons.	Under the first, ploughing commences as soon as the rains have set in and is continued till sowing time. Under the second, it begins soon after the rain or the autumn crop has been removed, the land being watered if necessary to admit of ploughing. The number of ploughings varies from fifteen to twenty in the west and from twenty to forty in the east, but when cane is grown immediately after the land has been cleared of a spring crop, it is not ploughed more than five times. After every ploughing, the land is levelled. Manure is usually applied before planting, and incorporated with the soil by ploughing in. Cattle-dung or farm-yard manure is generally used, and at the rate of 200 to 300 maunds an acre. In the east, canes which are intended to be cut up into "sets" are left standing in the field. A day or two before planting the canes are cut, stripped of their dry leaves, and left in water overnight. They are then chopped into pieces, each piece being about 15 inches long and containing three to five buds. In the west, in the Rohilkhand and Meerut Divisions, the top cuttings are planted, which consist of a portion of the top green leaves and a few of the upper joints. These cuttings are buried in a corner of the field and covered lightly with earth, a layer of dry leaves being placed above and underneath. Every fourth or fifth day, water is sprinkled over them to keep them moist. On the day of ploughing, they are dug out and removed to the field. If the moisture in the field is not sufficient, the land is usually irrigated before planting. Planting the sets is done in the following way. A first ploughing is made parallel to the side of the field, but only just scratches the soil, and is followed by a second which deepens the furrow. A man then places the sets along the furrow at a distance of about one foot from each other. A third plough brings up the rear and covers the sets with earth.
Seasons.	The time for putting the sets in the earth varies from the middle of February to the middle of April. The crop is watered three to seven times between planting and harvesting, and in a dry year more is necessary. Four or five days after planting, the first hoeing is done, and after every watering two hoeings are given. When the plants are very young, each hoeing is followed by levelling the ground, and after the commencement of the rains, or when the plants are about 2 feet high, the hoed field is again levelled. The number of hoeings varies from 7 to 14.
Ratoon Crop.	In the west and parts of the Doáb, the cultivators grow a ratoon crop, known as <i>péri</i> . To propagate the <i>péri</i> crop, the roots are left undisturbed from the time of first cutting, and the stripped leaves of the first year's crop are burnt in the field before the commencement of the rains. After the rains have set in and the young shoots begin to sprout, the field is ploughed up, the furrows being 6 to 9 inches apart. By the middle of November the crop is believed to have attained maturity and to be fit for crushing. Ordinarily, however, the cultivator does not commence cane-crushing till December.
Paundá Cultivation.	The cultivation of the variety known as <i>paundá</i> , grown almost entirely for chewing purposes, differs somewhat from the above. Before planting, the field is dug up one foot deep and the sets are planted earlier than the time stated above, since the sooner this variety of cane comes into market, the higher price it fetches. The method of planting is somewhat different. The sets in this case are dropped into furrows between ridges into which the field has been previously laid out, and are covered over with earth, the furrows being 24 to 36 inches apart and the distance between the cuttings about 2 inches. Poudrette instead of farm-yard manure is in this case generally applied, at the rate of 600 to 800 maunds per acre, or about three times as much as in the former case. The first hoeing is done as soon as the land gets sufficiently dry after the second watering. The field is then watered again, and subsequently the ridges are split and the field levelled and divided into irrigation-beds. Hoeings and waterings continue till the advent of the rains, and in July or August the plants are earthed up. The number of waterings varies from twelve to seventeen during the period of growth, and the number of hoeings from five to seven.

Cultivation

Hadi gives estimates of the cost of cultivation in the various divisions according to the second, the commonest method, and he states the lowest, that for Meerut Division, at Rs. 66; the highest, that for Rohilkhand, at Rs. 81 per acre. Speaking of the *paundā* canes, he gives the total cost as Rs. 157-8 per acre. [*Cf. Duthie and Fuller, Field and Garden Crops, 1882, i., 55-63, t. xiv.; Dist. Settl. Repts., U. Prov.; Moreland, Note on Sugar Cult., app., 4, xii-xxii.; Rept. on Sugar Cult. by Bihar Indigo Planters, 1901; Hadi, Sugar Indust. in U. Prov., 1902; Nevill, Dist. Gaz. U. Prov., 1903-5; Moreland, Sugar Indust. in U. Prov., in Agri. Journ. Ind., 1907, ii., pt. i., 15-21; Exper. Farm Rept., Cawnpore.*]

Panjab and North-West Frontier Province.—In the *Agricultural Statistics* for the year 1905-6, the area under sugar-cane is given in the Panjab as 172,700 acres, and the yield 88,983 tons, while the previous year was 325,500 acres and 238,300 tons of *gūr*, or about three-fourths of a ton to the acre. It has to be borne in mind, however, that in many tracts, especially with considerable Muhammadan populations, cane is grown largely, if not mainly, for eating purposes, and not used in the production of *gūr*. The more important district areas may be given for 1904-5, namely, Gurdaspur, which had 51,590 acres; Sialkot, 34,919 acres; Lyallpur, 30,672 acres; Jalandhar, 27,797 acres; Rohtak, 24,434 acres; Hoshiarpur, 24,021 acres; Gujranwala, 20,492 acres; Karnal, 19,553 acres; Delhi, 17,575 acres; Amritsar, 16,545 acres; Ambala, 15,870 acres, etc. The area in the North-West Frontier in the same year was 26,003 acres, the great bulk of which is grown in Peshawar, 18,414 acres in the year in question; Bannu, 6,387 acres; and Hazara, 1,094 acres. The area and production in 1906-7 were 257,600 acres and 212,800 tons in the Panjab; 28,600 acres and 32,800 tons in the North-West.

The following information applies particularly to Sialkot, one of the most important sugar districts of the Panjab, and is abstracted from the account given by Dunlop-Smith (*Gaz. Sialkot, 1894-5, 114-6*). The land which is to bear the crop must be frequently ploughed. In Sialkot the preparatory ploughings vary from ten to twenty, and the ground is always manured. Cane is never grown from seed. Each year, when a field is reaped, about 5 per cent. of the stalks are carefully selected and cut into lengths of about 9 inches and buried in a pit. They are ready for planting in about three months. When taken out of the pit they are placed lengthwise in the ground and pressed down with the foot. The ground bearing sugar-cane has to be kept moist by steady irrigation when there is no rain. But unirrigated cane is generally superior to that grown on well lands. Planting usually takes place in March. Before the crop ripens, it must be weeded about five times. Cutting begins in December and goes on intermittently for about three months. The quality of cane depends very much on the soil which bears it. The best cane is grown on the rich *darp* soils in Raya. The highly manured fields round the village sites bear a poor class of cane, though the outturn is very large.

When the cane is cut, the green tops (*ág* or *pánd*) are broken off and the sheaths (*chhói*) of the stalks are stripped with a sickle. The stalks are at once carried to the place where the press has been set up. The presses are of two kinds, wooden and iron. The former is a clumsy machine, sunk in a pit. The cane-stalks are made up in bundles of fifteen to twenty-five and passed through and through the press several times. The juice is received into an earthen jar sunk in the ground. The iron press is much simpler than the wooden, and stands above ground. As soon as possible after extraction, the juice is poured into a large flat iron dish (*karáh*) placed on an earthen oven, and boiled and stirred for two to two and a half hours till it begins to coagulate. When the mass is ready it is poured into a hole (*gand*) in the ground, carefully prepared by plastering with clay. The liquid is then stirred for some twenty minutes till it hardens and cools enough to be rolled into balls. [*Cf. Dist. Gaz. Pb. (especially Gujranwala, Rawalpindi, Shahpur, Montgomery and Multan); Rept. on Land Rev. Admin. Pb., 1901, ix., app. B, 111.*]

Central Provinces and erar.—Recent returns of the area and yield are not available for these provinces. The totals for 1904-5 were 21,398

	acres in the Central Provinces (19,601 irrigated, 1,788 unirrigated), and 2,076 acres in Berar. The districts with largest areas are usually as follows:—Central Provinces: Chhattisgarh (Sambalpur and Bilaspur), 8,730 acres; Nerbudda (Betul) 5,324 acres; Nagpur (Bhandara and Balaghat) 4,910 acres; Jabbalpur 2,425 acres; and Berar: Buldana, 922 acres; Wun, 350 acres; Basim, 342 acres, etc. Particulars are not available regarding the yield of <i>gúr</i> from these provinces collectively, but the <i>Revenue Settlement Report</i> on the district of Betul (published in 1901) affords many useful particulars that may be here mentioned. The average yield of cane would appear to be 18 tons and the yield of <i>gúr</i> about 2 tons (9 tons of cane yielding 1 of <i>gúr</i>). The <i>gúr</i> produced is, moreover, of excellent quality and fetches locally about 30 per cent. more than the average article imported from other parts of India. These results are no doubt higher than those obtained in the Central Provinces generally, and even in Betul the yield of <i>gúr</i> ranges from 1,500 to 5,000 lb. Sir J. B. Fuller proposed that the standards accepted for the yield of <i>gúr</i> should range from 1,500 lb. to 4,000 lb.
Field.	
Standards.	
Unirrigated.	Cane is grown under two quite different systems, according as irrigation is or is not used. The only soil on which it is possible to grow cane without artificial watering is that known as black cotton soil, and there is a certain amount of unirrigated cane in all districts in which this soil occurs. Unirrigated cane is planted in November, December and January, on land which has, as a rule, enjoyed a year's fallow and has been ploughed again and again for the previous nine months. The field is manured with cow-dung at the rate of 50 to 200 maunds to the acre, it being often applied as a top dressing when the young shoots have appeared above-ground. Pulverised oil-cake is also used in Bilaspur, being placed round the roots of the plants at the commencement of the rains. An important feature in this method of cultivating cane is the covering of the ground with leaves as soon as the young shoots have come up. This checks evaporation and renders the lack of irrigation less harmful than it would otherwise be. The field is hoed and weeded between the rows of cane three or four times during the rains, and the crop is ready for cutting in November. This system is known as <i>palwar</i> or <i>nagarwa</i> .
Planting Seasons.	
Manure.	
Mulched Surface.	
Harvest.	
Irrigation	But by far the largest and most productive portion of the cane area is irrigated. With water and manure, cane can be grown on almost any description of soil, but the kinds most preferred are clayey loams. The reddish loam of Chhindwara is one of the best suited to sugar-cane in these provinces. Montgomerie (<i>Land Rev. Settl.</i> , 1901-5, app. i.) takes a less favourable view, and says that the imports of cheaper sugars are curtailing production. He gives the cost of production as Rs. 164-10-10 and the average annual profit as Rs. 38. The following account of cultivation in Betul (abstracted from the <i>Rept. on the Land Rev. Settl.</i> , 1901, 32-40) will illustrate the method by irrigation. The field in which the crop is grown is divided into several plots, three or four in number, and the sugar-cane is grown in each in turn. It is generally irrigated from a well, but occasionally from a hole beside a river-bed. Before the rains, manure is laid down in the plot selected, and during the rains and the first months of the cold weather it is thoroughly ploughed. At the end of December or beginning of January the field is divided into numerous plots with main irrigation channels between and smaller ones across them. The furrows are made by a plough with a triangular board fastened above and at the back of the share. The "seed," which consists of pieces of cane each with three or four eyes, is then sown. The sower lays them in the water-channels, which have been previously well watered, and partly buries them by pressure with his foot. As soon as the plot is sown a watering is given, and if well-rotted manure is obtainable, it is now spread on the land. The crop is then fenced to keep out cattle and jackals. For the first fifteen days it receives no more water, but afterwards must be regularly watered. During the cold weather no part of the crop should be without water longer than eight days, and in the warm weather longer than four days. Throughout the monsoons there is nothing to do but keep down weeds, ward off animals and bind the canes together so that they may not be broken by wind. At the end of September watering must begin again, and great importance is attached to the watering given at this time. In

Cultivation

the middle of December the harvest begins. The first canes to be cut are those intended for use as "seed." The cutting and manufacturing of *gúr* commences in March. In the same *Report* it is stated that the best *gúr* is made from sugar-cane raised on soil that has never before borne the crop or been manured. As the land becomes more and more saturated with the dung which is annually put on it, the quality of the *gúr* gradually deteriorates, till it reaches the normal. When the crop is to be turned into *gúr*, the cane is dug up with a sharp pick. The leaves are peeled off and the stripped cane is then taken to the mill. Formerly the only mill known was a cumbrous wooden structure, but an iron mill is now in universal use. As the juice is extracted, it is poured into the evaporating pan. When evaporation is complete, in about six hours the juice is poured into a wooden trough sunk in the ground. After it has cooled and hardened it is hung up in cloths to drain, and in a couple of days is ready for the market. [*Cf. Fuller, Note on Outturn of Land under Crops in C. Prov., 1894, 24-46; Land Rev. Settl. Repts.*]

Rajputana and Central India.—The only States of Rajputana and Central India for which statistics are obtainable for a recent year (1905-6), and in which sugar is grown to any extent, are Gwalior, 5,221 acres; Jaipur, 645 acres; Bharatpur, 459 acres; Tonk, 340 acres; Kotah, 320 acres; and Alwar, 220 acres.

Rajputana
and
Central
India.

The systems of cultivation pursued differ in no material respect from those already detailed in connection with the Central Provinces and the Panjáb. In the *Dictionary* full particulars will be found of individual reports, but nothing of any great interest has since been published. The yield of *gúr* would seem to be about 30 to 40 maunds to the acre (28½ cwt.), and in some localities with good black soil and abundance of water (such as in Chitorgarh) as much as 50 maunds (36 cwt.) have been recorded. Ratoon crop is not uncommonly seen in these Native States.

Yield of *Gúr*.

Ratoon Crop.

Bo bay and Sind.—Sugar-cane is cultivated in almost all parts of the Presidency, and according to Mollison on a greater diversity of soil than is the case with any other irrigated crop. The area is ordinarily about 60,000 acres. In 1905-6 the actual area amounted to 56,333 acres in Bombay; 2,549 acres in Sind. In 1906-7 the area was 49,090 acres, and in 1907-8, 48,470 acres with a yield of 121,874 tons. In Bombay the chief centres of cultivation in 1905-6 were Poona, 12,204 acres; Sátara, 10,011 acres; Belgaum, 9,950 acres; Násik, 5,528 acres; Surat, 3,372 acres; Kanára, 3,004 acres, etc. In Sind, Karachi, 907 acres, and Hyderabad, 900 acres. In the *Report of the Department of Land Records and Agriculture* (1904-5, 6), the following observations occur:—"The sugar-cane crop in this Presidency is of small importance as regards area, but of considerable importance in regard to value. The United Provinces of Agra and Oudh have a million and a quarter acres under sugar-cane, and the Panjab and Bengal together have an equal acreage. We have only some 60,000 acres, but while their cane is largely grown without irrigation, and, even when irrigated, produces an outturn of not more than 2,500 lb. of *gul* per acre, the Bombay cane is always irrigated and produces an average outturn of 7,000 lb. of *gul*; with sufficient manure and skilful cultivation, near Poona, the outturn is known to reach even 15,000 lb. The cane crop pays a considerable part of the irrigation revenue on canals and is one of the most remunerative investments open to capital in Western India, the average net profit being reported to be about Rs. 150 per acre. Experiments have been in progress regarding the best methods of cultivation of this crop for ten years, and important conclusions have been published by Mr. Mollison and a pamphlet issued this year by Mr. Knight. These conclusions are (1) that excessive irrigation is ordinarily applied by cultivators from canals; (2) that water to the amount of 2½ to 3

Bombay
and ind.

Districts.

Yield.

High Profit.

Practical
Conclusions.

inches of rainfall should be applied every eight to ten days (these conclusions now regulate the Irrigation Department); (3) that the amount of nitrogen supplied per acre in manure should be about 350 lb.; (4) that this can economically be supplied by oil-cakes (this discovery has greatly influenced sugar-cane cultivation around Poona); (5) that the Poona system of cultivation in beds is better suited to the local cane than the system adopted from Mauritius."

Races Grown.

The cultivation of sugar-cane has thus been very fully discussed by the Agricultural authorities of the Presidency, and the following is mainly a summary of their observations, drawn for the most part from Mollison (*Textbook Ind. Agri.*, iii., 108-81):—The varieties cultivated may be broadly grouped into two, with numerous gradations between the extremes: (1) thick, juicy, soft kinds which require copious irrigation; (2) thin, hard, less juicy kinds which require lighter irrigation. Sugar-cane adapts itself to almost any kind of soil if drainage is previously secured, as a waterlogged condition is fatal. The season of planting varies in different localities. In Ahmadabad, Kaira and Baroda it is planted in May or early in June. In the Surat district, also in the Southern Maráthá country, most of the cane is planted in November and December, but the season may extend to February. In the Poona district, February and March are considered the best months to plant.

Seasons.

Soil.

Manure.

According to Mollison, the cultivation in the neighbourhood of Poona is typical of what it should be elsewhere, and he accordingly describes it in full. The best soil is a clay loam and the best preparatory crop a green-manure of *san* (*Crotalaria juncea*). The *san* should be sown thickly in June or July (about 70 lb. seed per acre), and ploughed in when $3\frac{1}{2}$ to 4 feet high. If no manure crop has been used, the land is allowed to lie waste during the monsoon. In November the field is deeply ploughed, and one or two subsequent ploughings are given in December. After ploughing, the surface is levelled with a log harrow, all clods broken, and manure applied. Poudrette or farm-yard manure, about 60 loads or 30 tons per acre, is most commonly employed. Usually, however, a smaller application is given before planting, and the crop is again top-dressed in June or July with such manures as castor-cake, *karanj*-cake (*Pongamia glabra*), fish manure, etc. Experiment has shown that the most important constituent of sugar-cane manures is nitrogen in immediately available conditions. Mr. Knight states that in the case of the *Pundia* canes, as much as 350 lb. of nitrogen per acre is required to give the best outturn. The manure should be evenly and carefully spread, and the land then ploughed into ridges 24 to 28 inches apart. The plough is next run across the ridges to form parallel water-channels 10 feet apart. Finally, the field is laid out in beds 10 feet square. Each compartment when complete contains four short ridges and five furrows. The crop is propagated from sets, though sometimes in other parts of the province, as in Gujarat, by planting whole canes. Each set has usually three eyes (buds) or more, and may be 15 inches to 18 inches long. One acre of good cane provides sets for 11 to 12 acres. Ratoon cane—i.e. cane grown from the root-stocks of the previous crop—usually provides the best sets, and many authorities consider the "tops" better for sets than any portion of the mature cane, but according to Mollison, it has yet to be proved whether the resulting crop is better or worse than from sets planted in the ordinary way. [*Cf. U.S. Dept. Agri. Exp. Stat. Rec.*, 1897, vii., 677; 1899, x., 546; 1901, xii., 438, etc.] The argument for using the tops is that they contain no cane sugar and that the practice of reserving whole canes for sets is wasteful. In the Poona district 16,000 to 18,000 sets are said to be required per acre. Before planting, water is conducted into each bed in turn. When it has partially soaked into the soil the sets are laid along the bottom of the furrows and trampled down 3 or 4 inches into the soft mud. The distance between sets is about 4 inches. Planting should take place in February and be finished before the middle of March. A month after planting, the land should be carefully weeded with a *khurpa* or hand-spod. Usually four weedings are necessary. In June or July new beds are formed. The soil is dug, levelled, weeded, and a second dressing of manure given. The canes originally planted in the furrows are earthed up with a hand-hoe, thus forming a furrow between the rows of cane. These furrows serve as new watercourses. After July or August, in the Poona district, cane requires no further attention except protection and irrigation. The land is first flooded as the sets are planted, and

Cultivation

thereafter two or three times at short intervals. Subsequently eight to ten days may elapse between the waterings, the shorter interval in the hot weather, the longer in the cold. The rainfall in the Poona district averages about 30 inches, and Mollison states that on an average sugar-cane gets during twelve months, in addition to the rainfall, irrigation water equal to 75 to 80 inches of rain, the crop being irrigated on an average 28 times a year. During the first three months the crop makes slow growth, and it is common to grow with it subordinate crops which ripen quickly, such as maize, *guvdr* (*Cyamopsis psoraleoides*), onions, cucumbers, melons and tobacco.

Subordinate
Crops.

It is difficult to judge by eye when the cane is ripe. Frequently a cane-grower tests the ripeness of his crop by a trial crushing and boiling. If a given quantity of juice gives a satisfactory weight of *gill*, harvest is proceeded with. Usually the crop gets a yellow colour as it ripens, but this colour may be caused by irregular or deficient irrigation or by a want of manure. If the side leaves are all dead, and the eye-buds almost to the top of the cane fully developed and firm, the cane is probably quite ripe. If it is intended to grow a ratoon crop, the cane should be cut with a sharp sickle at a height of 1 to 2 inches above-ground. Mollison states, on the evidence of experiments made at Mánjri, that it is risky in the Poona district to take more than one ratoon crop. Generally, however, in that district, two successive ratoon crops are taken. But Poona is the only district where ratooning is practised to any considerable extent. If no ratoon crop is desired, the cane should be uprooted and removed from the root-stock by a sharp jerk. It should be reaped or uprooted in the early morning, while the leaves are wet with dew. The dry leaves are stripped from the canes by means of a sickle. The upper green leaves, which are useful as fodder, are usually not removed in the field. Subsequently, the cane is tied in bundles and carried on the head or in carts to be crushed at the mill, which is often placed conveniently near the field. Forty tons per acre of cane is stated to be a fair average crop in Bombay. According to Mollison, the estimated cost per acre of cultivating sugar-cane by hired labour in Poona amounts to Rs. 486-12a. Mr. Knight gives as a general estimate Rs. 420-12a. per acre. In growing a ratoon crop, the cost is considerably less than for a new cane. No sets are required, less manure and less irrigation are necessary, and the saving amounts on an average from about Rs. 120 to Rs. 150 an acre. [Cf. Mollison, *Sugar-cane in Bomb. Pres.*, in *Agri. Ledg.*, 1898, No. 8; Knight, *Sugar-cane*, *Dept. Land Rec. and Agri. Bombay Bull.*, 1905, No. 25; *Repts. on Crop Exper. Bombay; Exp. Farm Repts. Poona*, 1896, 31-57, etc.]

Cost.

Madras and Mysore.—The area under sugar-cane in Madras, according to the *Agricultural Statistics* for 1905-6, was 74,359 acres, while an estimated area and yield for that year were 60,700 acres and 114,500 tons. It seems desirable to exhibit both the actuals and the estimates, since the yield (expressed from these quotations) would be 1·8 tons an acre. The largest district areas in the year named were Bellary, 9,761 acres; Coimbatore, 9,689 acres; Godávári, 8,413 acres; Trichinopoly, 7,430 acres; South Arcot, 6,168 acres; Vizagapatam, 5,763 acres; North Arcot, 5,585 acres; Salem, 5,045 acres; Cuddapah, 4,932 acres; Anantapur, 2,624 acres, etc. And it may be added these express relatively the ordinary areas of sugar-cane in the Presidency. Lastly, in 1906-7, 52,500 acres with a yield of 100,400 tons. The area in Mysore in 1904-5 was 38,802 acres.

Madras
Areas.

Districts.

The rich alluvial soils near the mouths of rivers are best adapted to sugar-cane, but the ground must be such that it can be irrigated for ten months of the year. During the first month of cultivation the field should be irrigated every week and afterwards every fortnight, but much depends on the nature of the soil. It is not usual to cultivate the cane two years running on the same land. In parts of Karnul, Tinnevely and South Kanara, however, the stumps of the cane are left in the ground to sprout and yield a crop the following year, and in the Nadyál taluk of the Karnul district, the cane is left in the ground for three years, and in the Cumbun taluk for as long as ten, the yield diminishing each year. These instances of slovenly agriculture are, however, exceptional. The cultivator usually permits land which has borne some other crop to lie fallow for a year, and then prepares it for the cane by several ploughings, or by breaking it up

Soils.

Ratoon Canes.

Propagation. with crowbars and by heavily manuring with whatever manure he can obtain. The crop is always propagated by cuttings. The top of the cane is commonly used, but some cultivators leave a few canes growing in the fields from the previous year, and cut them up into lengths of one or two joints. These tops or cuttings are placed horizontally in the wet soil about 18 inches from each other, in rows about 4 feet apart. Six days afterwards the field is again watered, and about the twentieth day, four or six shoots sprout from each cutting. In Ganjam and Vizagapatam some *raiyats* plant the cuttings in nurseries and afterwards transplant the shoots into the fields. After the shoots appear, the ground is weeded and hoed, and when they are about a month old, chaff, weeds, or some such manure is thrown around them. The soil is kept moist by occasional irrigation, and when about three months old the shoots ought to be 3 feet high.

Support. After this stage it often becomes necessary to give the canes support. This is done by fixing bamboos or saplings into the ground in the middle of each group of canes, the leaves being tied round so as to bind them together. Ten months from planting, the crop is ready for cutting. The cost of cultivation in the Presidency generally has been estimated at Rs. 150 per acre and the outturn at 22½ tons of stripped cane, yielding 45 cwt. of jaggery worth Rs. 250. Nicholson states the outturn of cane to be 25 to 30 tons, worth Rs. 150 to Rs. 200, and of jaggery 2 tons to 2½ tons, worth Rs. 210 to Rs. 240.

Cost.

Yield

The growing of sugar-cane in the Godáviri district, which was in former years a profitable undertaking, has in recent times suffered considerably from a disease which has attacked the canes, and a special Government station has been opened at Samalkota for the particular study of the disease and of cane cultivation generally. The objects of this experiment are laid down by Mr. Barber, Government botanist, Madras, in a note published in 1904 (*Exp. Sugar-cane Stat. Samalkota, Mad. Bull.*, ii., No. 48). The experiments carried on have made several points clear. Barber maintains that the quantity of water given to sugar-cane must be very carefully regulated, and that hitherto the cultivator has been in the habit of giving too much water. After each watering the land must be thoroughly and quickly drained. The highest and driest places must be chosen for the plantation and deep drains dug to throw the water off as quickly as possible, after the ground has been thoroughly soaked. Another important point is the selection of seed to safeguard the propagation from diseased stocks, and also to secure the introduction of new varieties exempt from disease from other parts of India and the world. Still another point that seems likely to assume the form of a radical departure is the cultivation of the sets in a nursery, preparatory to their being placed in the field. This is not a new principle to India, but has never been applied to any great extent. It has been recently decided that the farm shall be made permanent, and thirty-six acres of land have been acquired for the purpose. Further details regarding the work done will be found in an article by Barber in the *Indian Agricultural Journal* (1906, i., pt. i., 44-8; ii., pt. i., 33-41). [*Cf. Proc. Agri.-Hort. Soc. Mad.*, 1890, 44-60, etc.; Sturrock, *Man. S. Canara Dist.*, 1894, i., 207-8; 1895, ii., 139-40; Cox, *Man. N. Arcot*, 1895, i., 262-5; *Sugar-cane in Godáviri and Ganjam Districts*; Nicholson, *Man. Burma.
Areas.
Districts.

Bur. a.—The area under sugar-cane for 1905-6 was 2,281 acres in Upper Burma, and 10,429 acres in Lower Burma. In Lower Burma the largest areas are Thaton, 4,291 acres; Toungoo, 1,368 acres; Sandoway, 705 acres; Amherst, 688 acres; Kyaukpyu, 603 acres; Tharawaddi, 557 acres; Myaungmya, 447 acres, etc. In Upper Burma, Yaméthin, 1,587 acres; Kyauksé, 381 acres. These returns may be accepted as relatively correct for normal years.

The cultivation of sugar-cane in Burma was fully described (in 1885) by Mr. J. E. Bridges. We learn that the cane-producing lands may be roughly divided into two tracts: (1) that of shifting cane cultivation, where the cane is

CULTIVATION IN BURMA

ACC A U
FFICI A U
Manufacture

consumed in the raw state ; (2) that of permanent cultivation, where the cane is manufactured into *gür*.

The first tract includes roughly all the lands on the seaboard within the region of tidal creeks. The land, as a rule, is poor and will not yield a cane crop two years in succession, so that it is met with only in isolated patches. The form of cane grown is called *kyauktwin* or *kyaukchaung*, a large cane of light colour with short thick joints, so brittle that when passed through the mill it generally breaks at the joints. The timber on the land selected is cut down at the beginning of the dry weather, and burnt in March. Vegetables are then planted among the ashes and afterwards sold at a small profit. In September the land is cleared of weeds and cane pieces are placed in holes at a distance of 2 or 3 feet, the holes being in rows 3 or 4 feet apart. The cane-sets are fastened down by a bamboo lashing to prevent them being washed away. In January and February loose soil is thrown up round the young plants, and in May and June supports to which they are tied are placed near each cane-stool. In some parts trenches are made to admit water during the dry season and drain the land during the rains, and in other parts the plants are watered by bamboo water-lifts. About August and September the canes are cut and sold in pieces. If hired labour is employed, the cost of cultivation is Rs. 60 per acre.

Races Grown.

Seasons.

Cost.

The most important portion of the tract of permanent cultivation is situated in the valleys of the Bilin and Thébyu rivers. The soil here is almost entirely grey loam, mixed here and there with light clay. The land is covered during the rainy season by river floods for a few days at a time, and a thick layer of alluvium deposited on it. The soil on which cane is grown for manufacturing purposes in the other districts of the province is generally a deep rich loam. Where new land is cleared, or land already cultivated has been left fallow, the cultivator turns up the soil with a hoe at the beginning of the rains (May or June), and then leaves it to rest till September, when he digs holes 10 inches deep and one foot wide at intervals of 1½ feet from each other. Three pieces of cane (*agyaung*), about 5 inches long, are then placed in a standing position in each of these holes, and partly covered up with loosened earth. Some cultivators plough the land three times at the beginning of the rains instead of turning it up with a hoe, but the more general practice is simply to run deep furrows through the land in September, and then place the cane-pieces longitudinally along the bottom. The space between the furrows varies from 2 to 3 feet. Before planting, the land is cleared of grass and weeds. Ten days after the cane-pieces have been planted, the earth is loosened between the holes and the sets further covered with mould. In the beginning of January the earth is once more loosened and the plants again covered up. About May the land is once more cleared of weeds and the canes left till August or September, when they are stripped of old and withered leaves. They are ripe about the month of November in Burma proper, and are then cut close to the ground. The branches at the top are given to cattle as food and the tops preserved for planting. The remainder of the cane is divided into two pieces, tied up in bundles, and carried to the mill.

Soil.

Propagation.

Generally three or four young shoots, or ratoons, spring from the old stool. If these are sufficiently thick, no new plants are put down after the cane has been cut, but as a rule cane-tops are planted in the intervals between the ratoons, after the land has been cleared of grass and weeds. These tops are about 5 inches long and are planted from November to January. After the second year's crop the land is either left fallow for a year, or again is replanted with cane-tops and left fallow the following year. Mr. Bridges gives the cost of cultivation in a plantation worked entirely by hired labour as Rs. 90 per acre. The greater number of cultivators, however, work the land themselves with their families, and the average cost of cultivation is calculated at Rs. 15 to Rs. 20 per acre. With regard to the outturn of jaggery per acre, Capt. H. Desvoeux states that in the Kyaikto district (*Settl. Rept.*, 1898, 58) the average from *Class I.* soil is 2,984·05 lb.; from *Class II.* soil, 1,648·76 lb., and in the Toungoo district (*Settl. Rept.*, 1900, 57) the first-class average is 6,733 lb. per acre. [*Cf. Bridges, Sugar-cane in Brit. Burma*, 1885 ; *Settl. Operat. Repts. Burma* ; Max and Bertha Ferrars, *Burma*, 1900, 85 ; Nisbet, *Burma under Brit. Rule and Before*, 1901, i., 366, 445.]

MANUFACTU E.

INDIAN INDUSTRY.—Popularly it is often said that there are two main kinds of sugar—"Muscovado" (or raw) and "Crystals." The

anufac-
ture,
Indian.

Grades of Sugar.	former is refined or worked up into loaf sugar. In India a more comprehensive classification is necessary. The following are some of the chief grades, and the more generally used vernacular names for these :—(1) The CANE JUICE is <i>ras</i> ; (2) The REFUSE (MEGASS) is <i>pata</i> ; (3) The JAGGERY or RAW SUGAR is <i>gúr</i> or <i>gúl</i> (this is practically the MUSCOVADO of the West India planters), but when more carefully prepared and dried to a greater extent, it is sometimes clarified with lime and forms a sort of low-grade sugar. This is, in fact, the sugar of the well-to-do cultivators and middle classes of the population of India as a whole. (4) When intended to be refined, the juice is not boiled down to the extent of <i>gúr</i> , but is sold in a more liquid condition known as <i>ráb</i> . (5) MOLASSES and TREACLE are two grades of the uncrystallisable sugar drained from <i>gúr</i> , and to a less extent from <i>ráb</i> . They are known as <i>bhíra</i> , <i>choa</i> , <i>laptá</i> , <i>máth</i> , etc., for molasses, and <i>putri lát</i> for treacle. (6) COUNTRY SUGAR is a higher grade article than the sugar of (3) above. The juice has been boiled to a greater extent than for <i>gúr</i> , and on cooling it is stirred with a stick till it thickens. It is not, however, refined, though fairly well drained of its molasses, and is known as <i>lal-shakar</i> , <i>khanr</i> , <i>bhura</i> , <i>choyanda</i> , etc. (7) SUGAR REFINED. This is often called WHITE SUGAR. The <i>ráb</i> is generally boiled, clarified and the scum (<i>shíra</i>) removed, then drained of its molasses. It is at this stage called <i>pútri</i> , or, carried farther, it is washed completely free of molasses and then crystallised, when it is <i>khand</i> . For this purpose <i>pútri</i> is placed in a long conically shaped basket lined with fine cloth and suspended, water in a finely diffused state being the while made to pass through. The water is derived from a layer of moist aquatic weeds placed on the top for that purpose. The weeds part gradually with the water, which is seized by the sugar. The layer of crystallised sugar formed immediately below the weeds is again and again removed until the whole has been crystallised. In place of lime various other substances may be used in the clarification, such as the ashes of certain plants or impure carbonate of soda. Milk may be employed, as also the mucilaginous substances of certain plants, such as <i>Hibiscus</i> , <i>Kydia</i> , etc., or, more rarely, oils are added to the boiling <i>ráb</i> . These mucilages coagulate, and in doing so bind up the impurities which are then skimmed off.
<i>Gúr</i> .	
<i>Ráb</i> .	
Country Sugar.	
Refined Sugar.	
Diffused Water.	
Crystallised Sugar, or <i>Khand</i> .	
Qualities of <i>Khand</i> .	The various qualities of <i>khand</i> are recognised according to their position in the straining-basket. The top layer, the middle portion and the bottom, all constitute separate grades recognised in the trade. So also the <i>khands</i> of different localities have reputations of higher or lower merit. But the greatest possible diversity of opinion prevails as to the exact value of the names given to these different qualities. The clarifying and crystallising of sugar by the Native methods, thus briefly outlined, is supposed to involve such special knowledge that it is rarely attempted except by experts, and hence every village community possesses, or formerly possessed, its small refining factories. From the skimmings (<i>shíra</i>), as also the <i>pata</i> , vinegar is prepared in some parts of the country (see p. 1109).
Village Refineries.	
Vinegar.	

Misri.

Clarified.

Sugar-candy or Twice-refined Sugar.—In Indian trade three widely different substances are returned as sugar-candy—*misri*, *kuza misri*, and *chini*. In the preparation of all three, *khand* is dissolved in water, boiled, and milk used in its clarification. Slightly different systems of production prevail, but these need not be detailed. The result is the same, namely the white crystalline sugars known as *misri* and *chini*. These

are bleached and dried by exposure to the sun until they form fairly white and clean sugars. *Kuza khand* is alone the equivalent of the English sugar-candy. When this is to be prepared, the boiled and clarified *khand* is thrown into an earthen vessel in which have been suspended threads. The sugar on cooling crystallises on these and on the sides of the vessel in the form of large crystals. Certain localities are famed for their *kuza khand*, such as many parts of Rajputana, Bikanir for example.

Bleached.
Kuza Khand, or
Sugar-candy.

Crude though the methods may be which are pursued in the production of the various Indian sugar products, they very possibly give the suggestion of the original conceptions upon which the skilled art of sugar manufacture and refinement rests. In India, the canes of a certain neighbourhood are carried to a central locality where a crushing-mill, usually of two vertical iron rollers driven by bullocks, is owned in common by a group of cultivators. The cane is crushed and the juice boiled down there and then to *râb*, the *megass* being used as part of the fuel. The *râb* is then carried to the village or homestead where its further treatment is pursued, or it is sold to the dealers and in that form retailed, or is conveyed to the refinery, where it is worked up into sugar, etc.

The *Agricultural Journal of India* (ii., pt. i., which I have just received) contains three papers on sugar. Moreland deals very fully with the present position of the indigenous methods of sugar manufacture and the difficulties with which the manufacturer has to contend (*l.c.* 15-21). Lehmann gives many practical suggestions for the improvement of the methods and contrivances that prevail in Mysore. "The Indian sugar-cane," he says, "at least that grown in Mysore, is of excellent quality, and labour is relatively very cheap, less than one-seventh of what it is in Louisiana, where large quantities of sugar are produced notwithstanding that the quality of cane is very much inferior to ours. In the present method of manufacture heavy losses occur. The average of a number of experiments indicates that more than one-fourth of the total quantity of the juice is left in the refuse, that with a larger mill one-third of this loss can be saved (still larger mills would probably save two-thirds), that as much as 20 per cent. of the total sugar in the juice is sometimes lost by fermentation, and that, as a rule, over 13 per cent. of the total juice is lost by underliming. On the whole, the losses amount to at least one pound out of every five, that is, for every four pounds of sugar now obtained at least five could be got by stopping these heavy leaks, and probably the quantity of cane now giving three pounds of white sugar would as a rule give four pounds of such sugar when these losses are prevented."

Improvement.

"This would probably be quite sufficient to transform a crippled industry into a flourishing one. But there are further savings which can be introduced by manufacturing directly from the cane a sugar of much higher grade than is now being done when making jaggery. Part of this sugar, without being refined, could directly replace a portion, and possibly a very large portion, of the sugar now imported, and the rest could be sent to the refinery for conversion into the very highest grade of sugar, being thus transformed with a better outturn and at much less expense than an equal weight of jaggery."

Savings.

EUROPEAN INDUSTRY.—The stages, methods and appliances used in the European factories may be exhibited briefly as follows:—

Manufac-
ture,
uropean.

1. Extraction of Cane-juice.—The different methods pursued have been grouped under (a) Disintegration in crushing-mills; (b) Maceration; and (c) Diffusion.

By the last process, instead of being crushed in a mill (as already described), the canes are cut longitudinally in a slanting direction into slices one-sixteenth of an inch in thickness, by special cutting-machines. Very much less power is said to be required for this operation than for crushing by roller mills. The slices are then conveyed to an apparatus known as the diffusion battery. This consists of a series of cylinders, connected with each other, in which the sliced cane is subjected to water at a high temperature. This coagulates the albumen and extracts the sugar from the cells. It has been stated that 84 to 86 per cent. of the 90 to 91 per cent. sugar present is thus obtained, or about 20 per cent. more

Diffusion.

than by the roller system. The juice, moreover, is of greater purity owing to the coagulation of the albumen. The defecation of the juice is thus rendered far more simple and easy, and is eventually drawn from the battery free from glucose and of a pale straw colour.

Defecation.

II. Defecation and Clarification.—These operations consist of various stages, such as straining, heating, tempering, bleaching and filtering. The most important of these is defecation or tempering with lime (see *Li e*, p. 712) or other chemical substance, which, combining with the acids liberated, as also with any carbonates that may be present, precipitates these in the form of insoluble compounds (see *Alkaline Earths*, p. 58).

Concentration.

Crystallisation
in vacuo.

III. Concentration and Granulation.—The purified cane-juice has now to be freed of much of its water so as to allow of crystallisation. This may be accomplished by heat, either in open pans (the Native method) or in basins heated by steam or boiled in vacuum pans. In the last-mentioned process the grain formed from syrup boiled *in vacuo* is larger and more solid than from syrups simply concentrated to crystallising point in open batteries. Formerly the crystallisation was effected by cold, the Chevallier process.

Curing.
Bleaching.

Claying.

Centrifugal
Driers.

Improvement.

Effete Crafts.

IV. Curing.—The last stage embraces the complete drying and the whitening or bleaching of the sugar. This may be accomplished by simple drainage, as in the Native process above briefly indicated. In European trade, sugar simply drained of its molasses from casks placed over tanks was known as "Muscovado," "grocery sugar," "brown sugar," etc. The trade in this form is nearly obsolete. The claying of sugar corresponds with the washing with water derived from a layer of aquatic weeds. In the European method, a layer of clay used formerly to be placed over the sugar, upon which water was poured. The water percolated through the clay, removed the non-crystallisable sugar, the colouring matter and other impurities. The sugar was thus washed and, through the removal of the insoluble sugar, was in time also dried. But these and other primitive methods have been superseded in all the larger factories by centrifugal driers or hydro-extractors. There are many forms of this, but all consist essentially of a cylindrical basket revolving on a vertical shaft, its sides being of wire gauze or perforated metal. The basket is surrounded by a casing at a distance of about 4 inches, the annular space thus left being for the reception of the molasses expelled by centrifugal force through the sides of the basket, when the latter revolves at a high speed.

I prove ent of Indian Industry.—It would be quite possible to perfect the small hand factories of India to enable them to turn out at a cheaper rate than at present a much superior sugar. In many respects sugar manufacture and refinement are eminently suited for the hand labour and small capital of the village communities of India, but machinery and chemistry the world over are depriving all such communities of their handicrafts, and the salvation of the Indian sugar-manufacturing industry, it is feared, must be rather looked for in aids toward the establishment and encouragement of power factories, where the most advanced methods and contrivances will be used, rather than in subsidies to effete and wasteful crafts. Mr. H. F. Walker of Brisbane, Queensland, in a most instructive communication (*Bihar Sugar Comm. Rept.*, 1901, app. No. 5), discusses fully the system by which the industry has been substantially aided in that Colony. Moreland (app. No. 4) gives many

practical suggestions both as to methods of cultivation and systems of manufacture that might be adopted in Bihar. Minchin has strongly urged the Bihar planters to adopt the diffusion in place of the crushing system of treatment of canes. [Cf. Burkill, *Agri. Ledg.*, 1903, No. 8; Burkill and Weinberg, *Agri. Ledg.*, 1903, No. 12; Chapman, *Sugar, Encycl. Brit. suppl.*]

Perhaps one of the most hopeful directions of immediate improvement was dealt with by O'Connor, Hamilton and Handcock in their *Bihar Sugar Commission Report* (1901), where they discussed the advantages of the central-factory system. They studied critically the whole question of the cultivation of cane and the combined manufacture of sugar and indigo. While setting forth many agricultural and other reforms they advocated most strongly the adoption of the system of central mills and refineries as the most economical method of manufacture. But it may be urged that the possibility of the combination of two such widely remote technical industries as the production of sugar and of indigo, is the weak point of the scheme. Whichever proved the more profitable would secure the greater attention, until one or other might be ruinously neglected. Moreover, the power required for the one may very likely prove unnecessarily large and expensive for the other. But that reforms are not impossible with India generally can be seen from an inspection of the splendid results attained by Mr. F. J. V. Minchin at Aska in Ganjam. In 1852 he settled in that district, and in his own lifetime built up a great enterprise which has been described as having become the dominant feature of the trade and prosperity of a wide area. His example is one that might well be followed in every sugar-cane growing district in India both by Natives and Europeans, but in each centre a Minchin is required.

[Cf. *Second Ann. Rept. Agri. Chemist, Mysore*, 1901; Mukerji, *Handbook Ind. Agri.*, 1901, 384-91; Mukerji, *Improv. Sugar Indust.*, 1901; *Ann. Rept. Dept. Agri. Cent. Prov.*, 1904-5, 7-9; Hadi, *Improv. Native Methods Sugar Manuf., Dept. Agri. U. Prov. Bull.*, 1905, No. 19.]

By-products.—The by-products of the sugar factory are most important. The *megass*, or bruised canes, left after the extraction of the juice or *ras*, is in India usually employed as part of the fuel required for boiling down the juice. Minchin holds that by the diffusion process the whole of the sugar is removed from the cane, while by the Native process a large amount still remains. To prove this point, he purchased locally 40 tons of *megass*. Passing this through his apparatus, he was able to obtain from each ton 50 gallons of molasses, which yielded 30 gallons spirits of proof strength. Assuming an equal loss all over India, he made a calculation which he graphically represented by saying that the saving effected would go far to meet the interest of the public debt in India.

So again, it has often been said that the *megass* might be employed in paper-making; but in the greater part of India, at any rate, the difficulty of procuring firewood and the cost of collecting and transporting *megass* to the paper-mill would very possibly argue in favour of its present utilisation. In the United Provinces it was estimated that the fuel required for boiling and making the *gúr* from an acre of cane would be 108 maunds dry cane-refuse, 50 maunds dry cane-leaves, worth say Rs. 5, and about 5 maunds firewood worth Rs. 2. If firewood alone were used, 108 maunds, costing with cartage to the field say Rs. 31, would be necessary. There is thus a saving of Rs. 24 by using all the *megass* supplemented with firewood as compared with firewood only.

pirits.

Ru and Spirits.—The combination of a rum or spirit distillery with the sugar factory has been often maintained as highly profitable, and by the others used as an argument against the extension of sugar factories. Country brands of rum are said to be often coloured and flavoured in order to be sold as brandies and whiskies. The spirit produced pays a duty averaging from Rs. 4 to 6. The most important factory of this kind is the Rosa at Shahjahanpur in the United Provinces (see **pirits**, p. 1046).

Wall Plaster.

Chuna.—In passing it may be here mentioned that sugar is universally used in some form along with lime in producing the much-famed *chunam* plaster (see p. 293).

TRADE IN SUGAR.

Trade.

Centuries may be accepted as having intervened between the discovery of sugar and the time when it began to be a necessity of European life. We read of early transactions with India, which may be indicated by the following:—In Birdwood and Foster (*E.I.C. First Letter Book*, 338) mention is made in the commission of certain ships sailing for the East Indies in 1609, that they were to procure “sugars of the best some *twenty* chestes for a triall.” In a similar commission (1611, 407) we read again, “sugars of the best some *fewe* chestes for a triall.” In one of the Factor’s Records from Surat, addressed to Sir Thomas Roe in 1616 (Foster’s *E.I.C. Letters*, iv., 327), occurs the observation—“We deny not but that Bengalla brings wheat, rice, and sugar to Indya” (Hindustan proper), “makes fine cloths, etc., which showeth the fertility of the country and the quality of the inhabitants,” etc., etc. In a letter of date December 28, 1617 (*l.c.* vi., 280), Edward Monox threw doubt on the desirability of complying with the Company’s indents for Surat sugar. He urges that the sugar is a light, spongy article, “which I am persuaded with the damp of the hold coming into our moist climate will moulder and break to pieces and thereby prove unsaleable; besides it hath such an oily taste that it will not please our English palates.” Indian sugar, however, gradually assumed importance in Europe, and on cane cultivation being established as a European industry in the British Colonies, it obtained a fresh impetus. But the birth of the Colonial was the death of the Indian trade with Europe. The Honourable Company of East India Merchants becoming aware of the loss India had sustained in its failure to create, or even to participate in the greatly increased traffic, made strenuous efforts to awaken interest in the subject. Although many obstacles were thrown in the way, the Company succeeded in reviving and greatly enlarging India’s foreign interests in sugar. Heavy losses were for years patiently borne in the hope of ultimate success. East Indian sugar became regularly quoted, and it improved in quality as time went on. Moreover, the internal trade of India itself gave distinct indications of expansion. The demands of the people for superior qualities had grown so strong that the imported refined article gradually came to bear, in the various languages and dialects of the country, names that denoted the foreign countries of supply, such as *chini* (China) and *misri* (Egypt). There is, in fact, abundant evidence that for centuries the art of refining was not generally known to the people of India. According to Chinese records the knowledge would appear to have been derived from

Danger.

Oily Taste.

Colonial *versus* Indian Sugar.

India’s Foreign Interests.

East India Sugar Quoted.

Demands of India.

China.

Egypt.

Egypt, and according to Indian, most probably long subsequently, from China. A century or two ago the people of India, therefore, consumed a far larger proportion relatively of crude sugar (*gúr*) than they do even to-day. But the East India Company were wise in directing their attention to the internal trade: the demands of Bombay were obviously the most natural outlet for the surplus stock of Bengal, and the best check that could be given to the Dutch trade in supplying Bombay with sugar. But to facilitate this, the transit dues on sugar were removed and an import duty placed on the foreign supplies. Even when thus protected the Indian sugar did not, however, assume control of its own markets. Large supplies continued to be drawn from Egypt and China, as well as from Batavia and the Straits, and it was accordingly recognised that an effort must be made to improve the cheaper Indian refined sugar, more especially since still newer and more formidable producing centres had arisen in Mauritius and the West Indies which began to contest the Indian markets. And still more recently a disturbing element appeared in the supplies of cheap beet sugar, poured into India from Europe. Thus had India not only lost her European market but had become a field for European commercial enterprise in the provision of cheap refined sugar. But there has been secured at least one advantage of this new supply, namely the vigorous education of the people of India in the advantages of refined over crude sugar, and thus the opening out of a large market of which the Indian refineries have recently not been averse to avail themselves, and may do so still further in the future. It can thus be said that the people of India are able to pay a far larger sum not for sugar alone but for many other luxuries, than they ever did at any period of their past history. Further that the home market, by far the most important to the producers in India, is still largely secured to them. This is abundantly shown by the Finance Minister of India (*Gaz. of India Extraordinary*, March 21, 1906) by a table which exhibits the prices of refined beet-sugar at Calcutta and Bombay, and of Indian raw sugar at Cawnpore, for a number of years ending 1905. The averages of these for the past eight years would be—Calcutta, Rs. 10-14-7; Bombay, Rs. 11-7-0; and Cawnpore (*gúr*), Rs. 5-11-0.

Countervailing Duty.—It has been urged, moreover, that about the time beet-sugar first appeared in Bombay, a series of bad years, which culminated in the famine of 1901-2, curtailed Indian production and opened the door for foreign sugar. So firmly, at all events, have the foreign imports been established, that the trade is by many believed to be secure and to have given evidence of an expansion rather than a curtailment. A duty was accordingly imposed in March, 1899, on bounty-fed sugar from foreign countries. It was framed with the intention exclusively of countervailing bounties paid, directly or indirectly, by foreign Governments. This produced an appreciable revenue, which amounted in 1901-2 to 37 lakhs of rupees (and in the six years of its existence to 94½ lakhs); still, it did not stop the influx of cheap European sugar. The closing of the American markets diverted a still larger supply to India, and the Enactment of 1902 was intended to countervail this artificial surplus. The action of the Indian and American Governments thus forced the ratification of the Convention of Brussels. The immediate effect of the Indian duties was to diminish the sugar imports from Europe, and to divert the trade previously carried on with India by Germany and Austria, to countries which did not come within

the scope of the new legislation, and thus liberated fresh supplies of cane-sugar that poured into India. The imports of beet sugar in 1902-3 became about half those of 1901-2, while the imports of cane-sugar, which come mostly from Mauritius, Java and China, increased by more than 40 per cent. Finally, "in December, 1903, orders were issued remitting the counter-vailing duties chargeable on sugar produced, after August of that year, in countries which have limited their direct or indirect bounties on sugar, and their protective duties, to the minimum permitted by the Brussels Convention of 1902" (*Imp. Gaz.*, iv., 265). Sugar is thus now once more admitted into India free of all legislative restrictions, except the ordinary import duty of 5 per cent. on all foreign goods, and the counter-vailing duties against sugars produced in or exported from certain countries (Denmark, Chile, the Argentine Republic, Russia, etc.) which have not adhered to the Brussels Convention.

Sugar Free.

Areas of Consumption.

It may be said that the consumption of raw sugar is mainly in Northern India, and of foreign refined sugars almost entirely in Bombay, Calcutta and other large towns, more especially port towns. But it will be seen below, in the review of internal trade, that the railborne traffic manifests an expansion of the supply of refined sugar carried to the north, and thus to the regions of chief Indian production.

Mills.

Mills and Refineries.—According to the *Financial and Commercial Statistics*, there were 28 sugar factories in India in 1904 and 4,612 employees. Of these 19 were in Bengal with 1,772 employees; 6 in Madras with 1,979 employees; 2 in the United Provinces with 747 employees; and one in the Panjáb with 114 employees. The Government of India do not record any factories where less than 25 persons are employed, so that there are crude refineries, scattered all over India, not taken into consideration, that nevertheless turn out a certain proportion of the refined sugar used by the people of India. In Eastern Bengal (Jessore more especially) there are many small refineries chiefly concerned in the production of date-palm sugar. Similarly the indigenous refineries of Bihar and Shahabad are by no means unimportant, though apparently the trade has greatly declined through the competition of beet-sugar.

External Traffic.

External Traffic.—This resolves itself into two sections, Exports and Imports. It may be the most instructive course to deal with these more or less historically.

Exports.
British Import Duty.

1. **Exports to Foreign Countries.**—An import duty on Indian sugar, which was practically prohibitive, was imposed by Great Britain. It came to 8s. a cwt. more than was taken on Colonial sugar. This disability existed until 1836, the effect of which may be seen by the following figures:—In 1800 the British imports from India (expressed as raw sugar) came to 120,471 cwt. out of a total of 3,390,974 cwt.; in 1821 the corresponding figures were, Indian portion 277,228 cwt., out of a total of 4,063,541 cwt. Some twenty years later (1841, or five years after the removal of the disability on Indian sugar) the Indian exports to Great Britain became 1,037,501 cwt. In 1851 the corresponding exports from India to Great Britain were 1,506,051 cwt. (out of a grand total of 1,607,508 cwt. exported to all countries), but the next decade marked a great shrinkage, as the exports to Great Britain then stood at only 696,012 cwt. out of a total to all countries of 845,961 cwt. And these figures (though expressed on the basis of raw sugar, viz. 2½ to 1) mark the existence of a new disturbing element. The East India Company found in its early transactions that it only paid

Their Removal.

A New Departure.

to export the purer article, and indeed sugar (even of the finer qualities) was treated as a ballast cargo, to be used in place of saltpetre as occasion required. In none of the returns, therefore, were these exports raw sugar, though expressed as such. They were entirely Indian refined sugar, drawn from the indigenous refineries. It would not pay (so it was believed) to export raw or inferior sugars from India, the freights being then too high. With the growth of refineries in England and Scotland, however, combined with greater facilities of shipping and consequent cheapening of freights, it no longer paid to ship the refined sugars, and the consignments became more and more raw sugar to be used up by the British refineries.

Indian Refined Sugar.

English Refineries.

Raw Sugar.

The effect of this change may be briefly indicated. In 1877-8 the exports of refined sugar stood at 477,128 cwt. A sudden drop occurred in the next year, when these exports were only 51,043 cwt., and ten years later (1888-9) were only 34,523 cwt. But, correspondingly, the exports of raw sugar were in 1877-8, 366,997 cwt. The average for 1882-92 came to 1,145,685 cwt.; for 1892-1902, 733,654 cwt.; the actual for 1904-5, 192,890 cwt.; for 1905-6, 230,498 cwt.; and for 1906-7, 164,299 cwt.

Rise and Fall.
New Influences.

Thus there can be no doubt that a severe blow has been dealt to the Indian sugar industry, which, but for its own immense resources and recuperative power, might have been calamitous. Had England continued to purchase Indian raw sugar there is little doubt an immense expansion of the area of production, and an enhancement of the yield, would have been the natural consequences. All this is now changed, and sugar represents 53·3 per cent. of the total value of the articles of food and drink imported, and is the second largest single article of importation, the first being cotton piece goods. Thus the two chief items of India's early export trade have become her greatest modern imports.

Severe Blow.

Exports become Imports.

2. *Imports from Foreign Countries.*—It is perhaps not necessary to trace the history of the imports of sugar farther back than to the year 1871-2. India then received 562,559 cwt. of crystallised sugar. In 1881-2 the imports were 982,262 cwt. and in 1891-2, 2,734,491 cwt. Still a decade later (1901-2) they had become 5,565,272 cwt., and roughly in equal proportions of beet and cane sugar. Taking the traffic in both refined and unrefined sugars, the following year (1902-3) a shrinkage of the beet-sugar took place, the total imports being 4,987,195 cwt. (of which 3,529,678 cwt. were cane); in 1903-4 beet still further declined, the total having been 6,038,115 cwt. (5,485,378 cwt. cane); in 1904-5 the beet began to recover, and the total imports were 6,549,797 cwt. (4,833,309 cwt. cane); in 1905-6 they were 7,696,191 cwt. (4,263,798 cane and 3,432,393 cwt. beet); and lastly, in 1906-7, they were 9,730,713 cwt. (5,926,879 cwt. cane and 3,803,834 cwt. beet) (*Rev. Trade Ind.*, 1906-7, 8-9).

Imports.

Shrinkage of Beet Supplies.

Mr. Frederick Noël-Paton, Director-General of Commercial Intelligence, observes that beet-sugar continues to rule the Indian sugar-market; he further exemplifies the extraordinary vicissitudes of the trade by a statement of the imports of beet and cane sugar, month by month, during the year 1905-6. It is there shown that beet-sugar reaches India mainly in the months of November to March, the last-mentioned month being the most important, while cane comes more uniformly throughout the year, the chief months being August to October. Analysing the returns, it is found that 3,432,393 cwt. were beet, the average value of which was

Beet and Cane
u ars.

Arrival Seasons.

Respective
Prices.

9·2 rupees, while the share in cane imports came to 4,263,798 cwt. with an average value of 10·1 rupees; but in 1906-7 the averages came to Rs. 8·2 for cane and Rs. 8·7 for beet.

Influences
on Prices.

"The previous financial year closed in March, 1905, with the Bombay price at Rs. 13-15-0 per cwt. and the European price of 88 per cent. sugar at 13s. 3d. f.o.b. Hamburg. The highest point in recent years had been reached two months before that time, when Rs. 14-5-0 was recorded in Bombay. These high levels were due to several causes. The abolition of the bounties in European producing countries and consequent reduction of the internal sugar-taxes had led to a restriction of cultivation, and had induced such expansion of domestic consumption as had not been foreseen."

Decline
in Prices.

"But the high prices attained brought their own cure, for they induced at once an increase of some 16 per cent. in the acreage sown with beet in Europe, and also a resort on the part of consumers to reserve stocks of which the speculators had not had knowledge. After the opening of the financial year 1905-6 prices fell steadily, and they gave way completely about the month of July. Since July, the decline has been practically continuous. Since the close of the calendar year the price in Bombay had stood practically steady at Rs. 9-14-0 per cwt." (*Rev. Trade Ind.*, 1905-6, 5). In the following year (*i.e.* 1906-7, 8) Noël-Paton recorded the further stages in the decline already forecasted: "The price of 88 per cent. beet-sugar, f.o.b. Hamburg, was about 8s. 5d. in April, 1906, which is below cost. Refined beet in Calcutta at the same time was quoted at rates equal to 11s. 7d. per cwt., while the price in Bombay was 12s. 1d., and in Karachi 11s. 10d. Mauritius sugar in Bombay was at the parity of 11s. 5d. The highest for 88 per cent. sugar in London was 9s. 7½d., reached in September, while in Karachi refined sugar touched 12s. 4d. in October, and Calcutta was 12s. 7d. in November. Throughout the statistical year, Bombay remained steadily at 12s. 1d."

Cost Price.

Java.

Countries of Supply.—Of the cane-sugar supply perhaps the most significant feature is the rise and growth of the Javan contribution, very largely conveyed to Calcutta. In 1901-2 the total imports from Java were 446,686 cwt.; in 1903-4, 1,335,548 cwt.; in 1905-6, 1,685,391 cwt.; and in 1906-7, 3,304,366 cwt. A fair proportion of these were cheap unrefined sugars, No. 16 and under, intended to directly contest Indian production of *gûr*. The trade from Mauritius has for many years past manifested a consistent and almost uniform expansion. In 1901-2 it came to 1,759,203 cwt., in 1905-6 stood at 2,013,012 cwt., and in 1906-7 at 2,310,023 cwt. The only other country that need be mentioned is China.

Mauritius.

China.

The contributions from that country manifest extreme fluctuations, but on the whole seem declining. The highest record during the past five years was in 1902-3, while the figures for last year (1906-7) were the lowest, viz. 51,279 cwt. Of beet-sugar, Austria-Hungary is by far the most important source. As already mentioned, the years 1902-3, 1903-4, and 1904-5 manifested a marvellous curtailment, but the amount taken in 1901-2 was 2,257,928 cwt.; in 1905-6, 2,340,717 cwt.; and in 1906-7, 1,617,160 cwt. Commenting on these new aspects of the trade, Noël-Paton observes, "Of the refined sugar, Java, which in 1905-6 ceded the premier place to a beet-country, Austria-Hungary, resumes it (1906-7) with a quantity largely exceeding that ever before imported from a single country. She supplied, in fact, nearly 31 per cent. of the entire arrivals. The other cane country, Mauritius, follows with 24·61 per cent. of the

Austria-
Hungary.

total. Austria-Hungary, diminishing her contribution by nearly 723,500 cwt., drops to the fourth place with 17.53 per cent. of the total; and Germany, with the largest arrivals she has yet recorded, takes third place with 21.7 per cent.”

Thus it may be said that the Mauritius supplies of cane-sugar have hitherto been to Bombay what the Javan have been to Calcutta. But all the same, beet-sugar may be viewed as having begun seriously to contest both these markets.

INTERNAL TRADE.—Production and Consumption.—It has been estimated that India produces a little over one ton per acre of *gúr* (crude sugar), or $2\frac{1}{2}$ million tons for its total acreage, which, reduced to the standard of refined sugar, would be, say, one million tons. If the imports of about 400,000 tons be added, we obtain a total supply of $1\frac{1}{2}$ million tons of refined sugar. Divided by the head of population, this might be accepted as showing the consumption. But any such calculation would be most misleading, because (1) we have no sort of certainty as to the yield—a ton of *gúr* per acre seems absurdly low; (2) to the bulk of the people a pound of *gúr* very possibly serves the equivalent purpose of a pound of refined sugar to other communities; and (3) with a large percentage of the people of India *gúr* or sugar are unknown luxuries. It has been stated that the *per capita* consumption of India is 35 lb., a figure based on the assumption that the supply comes to three million tons, which from the above showing is probably double the actual amount. This is compared with European countries, such as Germany, where it is 28 lb., and France 24 lb. There is perhaps little to be gained by such calculations and comparisons. But it may be useful to examine the returns of *gúr* carried by rail and river as indicative of local production and consumption.

Traffic by Rail and River.—The internal trade is returned in cwt. and divided into two sections—(a) refined sugar and (b) unrefined sugar. The grand total of the movements of the former kind came in 1906–7 to 5,984,425 cwt. Fully three-fourths of that amount is usually distributed from the seaport towns, and thus includes (with local manufactures) the foreign imports. The shares taken were:—Bombay, 2,039,492 cwt.; Karachi, 1,863,451 cwt.; Calcutta, 1,248,595 cwt.; and Madras, 111,368 cwt. And these figures are relatively correct for at least the past five years. The CALCUTTA supply ordinarily goes to Eastern Bengal and Assam, 572,591 cwt.; to Bengal, 363,641 cwt.; and to the United Provinces, 235,573 cwt. The BOMBAY supply goes to the Bombay Presidency, 843,067 cwt.; to the Central Provinces, 367,255 cwt.; to the United Provinces, 358,530 cwt.; and to Rajputana and Central India, 241,363 cwt. The KARACHI supply goes principally to the Panjáb, 1,427,823 cwt., and to Sind, 345,593 cwt. But Calcutta has, however, manifested a remarkable expansion which is most significant. In 1900–1 exports from Calcutta by rail and river were 477,636 cwt.; in 1901–2, 505,789 cwt.; in 1902–3, 567,200 cwt.; in 1903–4, 839,210 cwt.; in 1904–5, 1,002,185 cwt.; in 1905–6, 1,059,416 cwt.; and in 1906–7, 1,248,595 cwt. This perhaps is the direct expression of the expanding foreign imports. Thus in 1900–1 Bengal (Calcutta mainly) imported 1,342,034 cwt. of refined or crystallised sugar, and that figure was gradually augmented until in 1904–5 it stood at 2,107,461 cwt., in 1905–6 at 2,197,303 cwt., and in 1906–7 at 3,305,860 cwt. The increasing importance of Calcutta in the foreign sugar trade is a feature of great consequence.

Early Records.

Of the consuming provinces it is curious to observe that in 1906-7 the Panjáb heads the list with 1,664,133 cwt.; then comes Bombay, 869,528 cwt.; the United Provinces, 712,559 cwt.; Eastern Bengal and Assam, 603,223 cwt.; Central Provinces, 487,717 cwt.; and lastly, Bengal, 465,493 cwt. These figures would seem somewhat at variance with the opinions often advanced (and mentioned above) that the imported sugars are mainly consumed in the regions of low Indian production. By way of illustration it may be mentioned that the imports into the United Provinces by rail were in 1900-1, 316,722 cwt.; in 1901-2, 492,921 cwt.; in 1902-3, 385,125 cwt.; in 1903-4, 614,355 cwt.; in 1904-5, 533,580 cwt.; in 1905-6, 752,091 cwt.; and in 1906-7, 712,559 cwt. These provinces are the headquarters of Indian cultivation, and even there foreign sugars seem to be finding a profitable market.

The traffic in UNREFINED sugar carried by rail and river came in 1906-7 to 9,420,832 cwt: The chief exporting centres (as might have been inferred from the *Agricultural Statistics*) are the UNITED PROVINCES with, in 1906-7, 4,054,814 cwt.: consigned to the Panjáb, 1,479,307 cwt.; Rajputana and Central India, 1,395,301 cwt.; Bombay, 363,912 cwt.; Bengal, 287,866 cwt.; the Central Provinces, 204,988 cwt.; the balance in smaller quantities. Next may be mentioned CALCUTTA with 1,958,828 cwt.: to Bengal, 1,005,932 cwt., and to the United Provinces, 468,063 cwt. Then BENGAL, with an export of 1,190,857 cwt.: sent to the United Provinces, 380,831 cwt.; Calcutta, 250,230 cwt.; the Central Provinces, 198,377 cwt.; Eastern Bengal and Assam, 159,380 cwt.; Rajputana and Central India, 121,374 cwt. The other exporting centre is MADRAS, 887,837 cwt.: to Madras ports, 361,693 cwt.; Bombay, 215,871 cwt.; and the Nizam's Territory, 137,659 cwt. We thus learn that Rajputana and Central India were the most important consuming provinces of the *gúr* carried by rail and river, viz., in 1906-7, 1,857,989 cwt.; then followed the Panjáb, 1,608,556 cwt.; then Bengal, 1,331,406 cwt.; next the United Provinces, 920,815 cwt.; Bombay, 822,158 cwt.; Central Provinces and Berar, 801,722 cwt.; and Eastern Bengal and Assam, 724,821 cwt.

Perhaps the most significant fact brought out by these returns is the dependence of Rajputana and Central India, as also of the Panjáb, for their supplies of *gúr* on the provinces of India, and for crystallised sugar on foreign countries. Another very striking peculiarity is the small share taken by the Madras Presidency in the returns of internal trade, a circumstance perhaps due to the greater success of the Aska and other Madras Presidency mills in meeting local demands.

Coastwise: also T ns-frontier.—These do not in any material respect modify the chief features of the internal trade, and need not therefore be here specially reviewed.

AL P.—The name given to the dried tubers of various species of orchids, such as *Eulophia* (D.E.P., iii., 290-1) and *Orchis* (D.E.P., v., 492-3). It is commonly known in India as *salab-* (or *salep*) *misri* (= Salep of Egypt).

According to the authors of *Hobson-Jobson*, salep is correctly identified by Ibn Baithar with the *satyrium* of Dioscorides and Galen. Perhaps the earliest reference to salep, in connection with India, is to be found in the *Voyages* of Ibn Batuta, of date 1340 (French ed., 1855, iii., 382), where amongst the provisions given to the travellers by the Sultan of Delhi, *salip* is mentioned. Again, Alexander Hamilton (*New Acc. E. Ind.*, 1727, i., 124-5) speaking of Tatta on the

river Indus, says: "They have a fruit, that grows in their fields and gardens, called *salob*, about the size of a peach, but without a stone. They dry it hard before they use it, and being beaten to a powder they dress it as tea and coffee are, and take it with powdered sugar-candy. They are of opinion that it is a great restorative to decayed animal spirits." The article obtained in the Indian bazárs has been ascertained to be chiefly the product of several species of *Eutopha*, viz. *E. campestris*, *E. nuda* and *E. rivens* (*markand* or Lahore salep of the shops), though probably also from the species of a few other genera, and is produced on the hills of Afghanistan, Baluchistan, Persia and Bokhara; but the Nilgiri hills and Ceylon are said to furnish part of the Indian supply. The salep of European commerce is procured chiefly from the Levant, and to some extent from Germany, etc., derived mainly from the tubers of *Orechis mascula*. The tubers are dug up after the plant has flowered; and the plump, firm ones are washed and set aside, and subsequently strung on threads, scalded, and dried in the sun or by artificial heat. The commercial article is met with in three forms—palmate, large ovoid, and small ovoid.

Indian
Articles.

European.

Various substitutes are sold in India. The kind known as Royal Salep (*bádshah sáláb*) has been identified as being derived from a species of *Allium* (*A. Macleanii*, Baker, *Bot. Mag.*, t. 6707; Aitchison, *Annals of Botany*, 1889-90, iii., 149-55): while the tuberous roots of *Asparagus adscendens* (West Himalaya and Panjáb) and of *A. racemosus* (Deccan) are the white *músali* (*D.E.P.*, i., 343-6); *Cucurbitigo orchitoides*, the black *músali* (*D.E.P.*, ii., 650-1), and certain species of *Habenaria* are also so used (Watt, *Comm. Letters, Upper Ind.*, 1899, 13). Besides these substitutes an imitation salep, made of potatoes and gum (known as *banawati salab*), is largely manufactured for the Indian market.

Substitutes.

A considerable Trans-frontier trade exists in salep from Afghanistan, Persia, Baluchistan and Bokhara into India. A little trade is also done in collecting and drying in India itself, mostly Kashmir and Lahoul, the tubers of *Orechis latifolia*, but the bulk of the ordinary article met with in the country is imported by sea into Bombay from Persia and the Levant. [*Cf.* Milburn, *Or. Comm.*, 1813, i., 108-9; *Pharmacog. Ind.*, iii., 384-7.]

Salt.

istory.—Salt in India is perhaps contemporaneous with the birth of Indian agriculture. Its most ancient Sanskrit name, *Lávana*, has few, if any, other meanings than salt or saltiness. Susruta, the father of Indian medicine, speaks of four kinds of salt, and these correspond with the four chief grades known to-day, viz. *Saindhava*, the rock-salt of Sind and Kohat; *Sámudra*, produced from the sea; *Romaka* or *Sákam bari*, Sambar Lake salt; and *Pánsuja* or *Ushasruta*, salt produced from saline earth. In modern commerce, according to Mr. A. S. Judge, there are in Calcutta some thirteen forms or grades of salt, as for example:—

History.

(1) English *panga* salt, imported from Liverpool, Middlesborough, Hartlepool and Bristol—the bulk coming from the mines of Cheshire. This is consumed in the greater part of Bengal and Assam. (2) Hamburg—*a* rock salt obtained from the mines. (3) Aden *karkach* salt, manufactured from sea-water by solar evaporation. (4) Aden crushed salt. (5) Rawayah *karkach* salt—this comes from the African coast of the Red Sea. (6) Rawayah crushed salt. (7) Salif *karkach* salt—this also comes from a port (Salif) on the African coast. (8) Salif crushed salt. (9) Salt from the Persian Gulf—this used to be brought by the Arab sailing-ships, but as these are rapidly disappearing the trade is on the decline. (10) Bombay *karkach* salt. (11) Spanish *karkach* salt—this is im-

Modern
Grades.

Influence
of Transport.

ported from Tarravieja in Spain and is obtained by solar evaporation. (12) Port Said *karkach* salt. (13) Madras *karkach* salt—this is imported by Calcutta from Coconada, Vizagapatam and Tuticorin. It is obtained by solar evaporation, has a brown appearance, is gritty, and accordingly not much in demand.

Although India possesses a mountain range of rock-salt, immense beds of salt-bearing soils and a vast extent of salt lakes, as well as many hundred miles of sea-coast where sea-salt might be manufactured, the conviction prevails that it will not pay to carry salt over more than some 300 to 400 miles, by internal routes, from any centre of supply. Moreover, the export traffic of India originates shipping that practically conveys salt as a ballast cargo, the profit being in the return cargoes. It is on these and such-like considerations that Bengal has always been largely dependent on external sources. Owing to the immense amount of fresh water poured into the Bay of Bengal, it does not pay to manufacture sea-salt near Calcutta.

Supply.

ources of Supply.—Holland gives the following classification :—

“(1) Sea-water, from which 61·8 per cent. of the total production was obtained during the period (1898 to 1903) ;

“(2) Subsoil water and lakes in areas of internal drainage, in both of which the origin and mode of concentration of the salt are the results of essentially similar natural processes. From these sources about 27 per cent. of the total was obtained ; and

“(3) Rock-salt beds, from which 11·2 per cent. of the total was obtained by mining and quarrying.”

Mining.

Salt Mining in India.—There are three chief centres—the Salt Range of the Panjáb, the Kohat hills, North-West Frontier Province, and Mandi State in Kangra district, Panjáb. These have produced, for the five years ending 1903, the annual average of 109,000 tons, of which 81 per cent. is obtained from the Salt Range, 14·5 per cent. from Kohat, and 4·3 per cent. from Mandi.

The following particulars may be here given from Holland (*l.c.*, 1905, 83–5) :—

alt Range.

“The chief deposits of rock-salt are in the so-called Salt Range of the Panjáb, where the seams of salt and included marl partings have, where worked in the Mayo mines at Khewra, an aggregate thickness of 550 feet, of which five seams of pure salt make up 275 feet, the rest, known as *kolar*, being too earthy and impure to be marketable. These beds occur in a formation lying directly underneath beds of Lower Cambrian age, but it is suspected that they may be of Lower Tertiary age, like the other salt deposits of this part of India, and that they have arrived in their present apparently anomalous position by an overthrust of the older fossiliferous beds.

“Mining for rock-salt is carried on in the Mayo mines, Jhelum district, the Warcha mines in the Shahpur district, and across the Indus at Kalabagh. The rock-salt in this area varies from white to brick-red in colour, and thus differs in colour from that of the Kohat area.

“The most important of the mines in the Salt Range are the Mayo mines near Khewra (32° 39' ; 73° 3'). In this area salt-quarrying was practised for an unknown period before the time of Akbar, and was continued in a primitive fashion until it came under the control of the British Government with the occupation of the Panjab in 1849. In 1872 the system of mining was reorganised, and the work now in operation was planned out by Dr. H. Warth, late Deputy-Superintendent, Geological Survey of India.

“The rock-salt being raised in the Mayo mines has, on account of its purity, a wide distribution. A recent analysis of one of the seams gave the following results :—

Sodium chloride	98·86
Sodium sulphate	0·57
Sodium carbonate	trace
Magnesium chloride	nil
Moisture..	0·08
						<u>99·51</u>

"In the Warcha mine, Shahpur district, the seam of rock-salt being worked is 20 feet thick, with a one-foot parting of marl, dipping 30° to the N.N.W.

"About two miles E.N.E. of Kalabagh on the Indus, rock-salt is worked in open quarries on the east slope of Sandagar hill.

"The rock-salt raised in the Cis-Indus mines and Kalabagh quarries is principally consumed in the Panjab and North-West Frontier Province. During the past six years the average annual sales in these provinces amounted to 70,964 tons, or 82·3 per cent. of the total. In the same period the rock-salt sent to the United Provinces averaged 10,049 tons a year, or 11·3 per cent., whilst as much as 5·7 per cent. of the total sales, or an annual average of 4,933 tons, reached as far as Bihar, and small consignments of about 10 tons a year were despatched to Lower Bengal. The average annual amount of 580 tons which entered Sind formed 0·7 per cent. of the sales for the years 1897-8 to 1902-3.

"The Kohat salt is grey in colour with transparent patches. It is worked in open quarries, and the masses exposed may be regarded as practically inexhaustible at the present rate of output. In the anticlinal at Bahadur Khel, where the salt is seen to be at the base of the Tertiary system, the beds can be traced for a distance of about eight miles, with an exposed thickness of over 1,000 feet.

"In Mandi State, rock-salt is worked in open quarries near the faulted junction of the Tertiary and the older unfossiliferous rocks at Guma and Drang. The Mandi salt is of a dirty plum-colour, containing earthy impurities which bring down the available sodic chloride to 60 or 70 per cent."

Salt-evaporation in India.—This may be referred to two sections—
(a) direct evaporation of sea-water; (b) subsoil and lake brine. The former is chiefly conducted at Bombay and Madras, these two presidencies usually contributing between them about two-thirds of India's total salt supplies. Holland (*l.c.* 89-91) observes:—

"Of the salt produced in Bombay, about 78 per cent. was obtained from sea-water, the rest being manufactured from subsoil brine at Kharaghora and Udu on the border of the lesser Rann of Kach, and possibly derived from infiltrated sea-water. The Madras salt is practically all made from sea-water, a very small quantity of spontaneous salt being collected at Pandraka in the Masulipatam Sub-division.

"The chief manufacture of salt in Burma takes place also along the sea-coast, but subsoil brine is evaporated at various places in Upper Burma, notably in Lower Chindwin, Sagaing, Shwebo, Myingyan, and Yamethin districts, and in smaller quantities in Minbu and Meiktila, as well as at Mawhkeo in Hsipaw State. During the past six years the average annual production of this salt in Burma has been 3,432 tons."

"In Sind 88 per cent. of the salt raised during the years 1898-1903 was obtained from sea-water, and 12 per cent. from the Saran and Dilyar deposits on the edge of the great desert."

"The second form of occurrence" (subsoil and internal lake brine) "is characteristic of areas in which evaporation of rain-water is excessive compared to run-off, and the salt recovered in these areas is that merely arrested on its journey to the sea, where, in the same way, it is concentrated by evaporation of the water. The most prominent of such areas is the desert-belt of Rajputana, including the salt-lakes of Sambhar, Didwana, Falodi Lonkara-sur and Kachor-Rewassa, with a brine-impregnated subsoil along the whole valley of the Luni, as well as the country to the west in Sind around the Rann of Kach and the delta of the Indus. To the north of the Rajputana country subsoil brine is raised and evaporated for salt in a cluster of villages in the Sultanpur mahal, south-west of Delhi. Other places occur in parts of the United Provinces and in Berar, where large quantities of salt were formerly obtained from subsoil brine in the alluvium of the Purna river. In Gwalior State salt is regularly manufactured from subsoil brine, the average annual production during the years 1898 to 1903 having been 434 tons. In Bihar a small quantity of salt is separated in the manufacture of saltpetre." The returns for the past four years in Bengal show an average of 106 tons per annum produced.

Sa bhar Lake.—F. Ashton (*Agri. Ledg.*, 1900, No. 13), Deputy Commissioner of Northern India Salt Revenue, wrote a brief account of the salt industry of India, also a highly instructive and copiously illustrated statement of the Sambhar Lake salt and the other salt works of

Rajputana (*Journ. Ind. Art Indust.*, 1901, ix., No. 73). He tells us that the salt industry of Rajputana produces about 200,000 tons a year and meets the requirements of 59 millions of people. The Sambhar Lake, it is believed, has been worked for salt for the past 1,400 years. It is about 20 miles in length, the breadth varying from 2 to 7 miles, and it covers an area of 90 square miles. The surrounding country is sandy and sterile, with the great Indian desert to the westward. The density of the lake brine varies with the annual accumulation of water. In years of normal rainfall it is about 3° Beaumé (the density of sea-water), but when very full is considerably less, and during years of drought it may be as high as 10° Beaumé.

The lake was taken over by the Indian Government in 1871, and since that date has yielded 4 million tons of salt. It lies within the boundaries of the Native States of Jaipur and Jodhpur. Holland remarks that "the Sambhar Lake is a silt-filled depression in the Aravalli schists and gneisses, in which a body of mud and sand with *kankar* and gypsum (some 75 feet thick in what appears to be about the centre of the depression) includes from 2 to 12 per cent. of sodic chloride, with smaller quantities of sodic sulphate, sodic carbonate and potassic sulphate. Every year the water brought in by the rivers, which are in flood during the monsoon, forms a lake some 60 square miles in area and 2 to 3 feet deep. The water, which is fresh when it first comes in, takes up salt from the accumulated stocks in the silt and forms a strong brine, which is partly led into prepared enclosures (*kyars*) for the separation of the salt by solar evaporation, partly isolated by temporary reservoirs constructed and cut off bodies of the lake-water in anticipation of the recession towards the centre during evaporation, and partly forms a thin crust of white glistening salt on the bed of the lake, where it is allowed to remain until the arrival of the next monsoon and the usual annual flooding of the lake."

"During the past few years the quality of Sambhar salt is said to have depreciated, and it has been suspected that the large quantities which have been removed have at last made an impression on the great stores of salt which must have accumulated in the lake silt, appreciably raising the proportion of the associated compounds sodium sulphate, sodium carbonate and potassium sulphate."

In the *Records of the Geological Survey* (1905, xxxii., 81; xxxiii., 100-2) will be found a highly instructive refutation of the opinion that the supply from Sambhar was decreasing. "The rise in the proportion of other salts is small and possibly at present unimportant; the rise in the level of the silt is perhaps more serious; but, whatever may be the cause, it would be humiliating to watch the failure of this lake, when one knows for certain that it contains, in its uppermost 10 feet of silt, enough salt to supply the requirements of this section of the Salt Department for another 300 years."

Ashton explained that the manufacture of salt at the lake is dependent upon the monsoon rainfall. "This," he says, "greatly varies from year to year, and the outturn of salt fluctuates in accordance with the quantity of the brine in the lake. The greatest quantity produced in any one year has been about 260,000 tons, and during a year of excessively heavy rainfall only about 3,300 tons were obtained."

After Sambhar, the Pachbadra salt source is next in importance. This is situate in Jodhpur (Marwar, as it is well named—the land of death).

The town of Pachbadra has a population of 5,000, and stands on the right bank of the Luni (the salt) river and at a distance of 40 miles from the city of Jodhpur. The salt is found in the upper end of a sand-valley, the salt-bearing tract being about six miles long and under two miles wide. All over that area brine-springs exist, and from these the salt is manufactured. In 1878 the Government of India purchased by annual subsidy complete control of these brine-wells, the production of which is about 30,000 tons. Pits of an average length of 230 feet and a breadth of 60 feet are dug to the level of the brine-springs and become filled with brine to a depth of 3 feet. Thorny branches of *Lycium europæum* are thrown into the pits and the salt precipitates on these, thus causing more flow of brine. The density of the brine varies from 20° to 25° Beaumé.

Purchased by Government.

Collection.

The salt source of Didwana is also situate in Jodhpur at a distance of 40 miles N.W. of Sambhar Lake. The supply of brine is abundant and believed to be inexhaustible, and in the dry climate of the desert manufacture could be carried on for nine months of the year. The rainfall has no effect on the salt-producing capabilities of this source. Since the Government acquired sole rights (1878) about 300,000 tons of salt have been made. The cost of production comes to 10*d.* a ton and it is sold at 1*s.* 8*d.* a ton, but the want of sufficient means of transit restricts the traffic. The Didwana salt is practically all consumed in Rajputana and the adjoining districts of the Panjáb. During the years 1897 to 1903 the annual average production came to 10,502 tons.

Didwana.

Rainfall no influence.

Government Acquired.

Production.

These salt-wells thus occur in what may be viewed as a former bed of the Luni river; and lower down in the present basin, just before the river debouches into the Rann of Kach, a large delta is formed through which during floods numerous channels carry the waters to the sea. In the dry months of the year, when the bed of the main stream is perfectly dry, brine percolates into the tributary channels and salt is formed naturally in thousands of tons annually, only to be swept away when the river comes down in torrents with the monsoons.

Kach.

THE SALT DEPARTMENT.—In 1894 the Government of India had a Memorandum prepared, as a conspectus of the systems and methods of the administration of the Indian salt revenue in all its branches and in all provinces. There may be said to be four centres of administration—(1) Bengal, (2) North India, (3) Bombay and (4) Madras. These are briefly as follows:—

salt Department.

1. *engal.*—"Bengal and the greater part of Burma obtain their salt by importation. Under the Muhammadan rule a tax was levied on salt by means of imposts on the privilege of manufacture, and by duties on the transport of salt from the places of manufacture to the interior of the country. Later on a system was gradually matured which provided for the control, the manufacture, and sale at the agency to the Company's servants. This was introduced by Clive and perfected by Warren Hastings in 1765 to 1780, and it survived in a modified form till 1862. A Government salt monopoly similar to that which existed in Bengal was introduced in the Madras Presidency at the beginning of the 19th century. In Bombay salt did not become a considerable source of revenue till 1837.

engal.
Muhammadan Rule.

Warren Hastings.

"The trade in Cheshire salt rose to importance about the year 1835, and thenceforward imported salt gradually ousted the Native product in Bengal proper, until by 1873-4 local manufacture had ceased and the accumulated stocks had become exhausted. The dampness of the climate

Imported Salt.

Liverpool.

and the large amount of fresh water discharged into the Bay of Bengal by the Ganges and the Brahmaputra tell against efficient salt-manufacture on the Bengal coast, but the manufacture of salt was not finally abandoned in Orissa until 1898. Nearly half the salt imported into Bengal comes from Liverpool, and the rest principally from Germany, Aden, Maskat, Jeddah, Bombay and Madras. Since the construction of the railway along the east coast, Madras salt transported by land has begun to compete successfully with the imported commodity." [*Imp. Gaz.*, iv., 248; Geake, *Repts. Admin. Salt Dept. Beng.*, 1906; Keith, *Repts. Admin. Salt in Burma*, etc.]

North India.

2. *North India*.—This embraces the United Provinces, the Central Provinces, Rajputana, Central India, the Panjáb, and the North-West Frontier Province. Its sources of supply are Sambhar, Didwana, Pachbadra and Sultanpur evaporation works, and in addition the salt-mines of the Salt Range of Kohat and Mandi.

Action of Sikhs.

Under the Sikh Government salt was one among forty-eight articles liable to customs, excise, town or transit duties. But the Sikh Government did not establish any system of management nor a fixed scale of duties. Since taken over by the Government of India the manufacturing and preventive operations have been directly controlled by the Northern India Salt Department. "Along with salt duties, the British administration

Transit Duties.

inherited an immense number of transit duties, levied at intervals along the trade routes under a system requiring elaborate customs arrangements and involving an intolerable hindrance to trade and communication. In 1843 the transit duties, with the exception of those on cotton and sugar, were abolished, and the loss of revenue was partly made up by enhancing the Provincial salt duties. The cotton duties were abolished in 1855, while the salt duties were gradually raised until in the period from 1869 to 1877 the salt tax in Lower Bengal was Rs. 3-4 a maund, in the Upper Provinces Rs. 3, in the country beyond the Indus a few annas, and in Madras and Bombay, Rs. 1-13 a maund. The salt sources of Rajputana belonged to the Native States in which they were situated, and duty was levied on their produce when it crossed the frontier. These arrangements

Cotton and Sugar Duties.

Customs-line.

could be maintained only by stringent preventive measures. To prevent untaxed Rajputana salt, and the lightly taxed salt from the south and west, from coming into Northern India, it was necessary to maintain a customs-line extending for nearly 2,500 miles, from Torbela, near Attock on the Indus, to the Sambalpur district of Bengal. The line was guarded by an army of nearly 13,000 officers and men, and consisted, along a large part of its course, of a huge cactus hedge supplemented by stone walls and ditches. It must be remembered, however, that this line took the place of a more annoying system of innumerable customs ports scattered throughout the interior of the country."

Abandoned.

"In 1870 the Government of India acquired a lease of the Sambhar Lake, with a view to increase and cheapen the supply in the United Provinces; and in 1874 over 760 miles of the eastern portion of the line were abandoned, the trade in this direction having concentrated itself on the railway route. The necessity of changing the whole system was at the same time indicated by Lord Northbrook, and a few years later Lord Lytton's Government was able to acquire the remaining salt sources of Rajputana and to equalise the duties throughout the greater part of India. Treaties were made by the Native States concerned, and in 1878 the Bengal

duty was lowered to Rs. 2-14 a maund, and the duty in Northern India to Rs. 2-8. At the same time the duty in Madras and Bombay was raised from Rs. 1-13 to Rs. 2-8 a maund. The whole customs-line was abandoned in 1879, with the exception of a portion along the Indus, maintained to prevent the still lightly-taxed Kohat salt from being smuggled across the river" (*Imp. Gaz.*, iv., 250-1). [*Cf. Repts. Admin. N. Ind. Salt Dept.*; Drew, *Jummoo and Kashmir*, 297-301; Lawrence, *Valley of Kashmir*, 1895, 393-5.]

3. **Bo bay.**—Salt is produced in Bombay for local consumption and for export both by land-routes and sea to Central India, Rajputana, the Central Provinces, the United Provinces, the Nizam's Territory, Malabar, Madras, Bengal and the Straits. Under existing arrangements exports, both by land and sea, pay full excise duty to Bombay. By an Act of 1837 the manufacture of salt was placed under restrictions, and both locally manufactured and imported salt were subject to a duty of 8 annas a maund. This was gradually raised until in 1888 it had become Rs. 2-8, and in 1903 was reduced to Rs. 2, and in 1905 to Rs. 1½ per maund. The excise system is followed, viz. licenses are issued to private manufacturers at approved places which are guarded, and whence no removals are allowed except on payment of the duty. In Gujarat all the works in British territory are the property of Government. The two chief centres are Kharaghora on the borders of the Rann and Dharásna on the coast of Surat. The Kharaghora salt is in large crystals made from brine-wells. [*Cf. Admin. Repts. Bomb. and Sind.*]

4. **Madras.**—Madras salt is practically all made from sea-water. Little is known of the salt system of Madras prior to the establishment of the Government monopoly in 1805. Under this system private manufacture was permitted, but all the salt made had to be sold to Government. The salt was resold by Government at a price calculated to include purchase-money, storage, transport and other charges reduced to an average for the whole Presidency. Later on the excise system was introduced, but this has never been enforced universally, and hence there are two systems, one in which the produce has to be sold to Government, the other in which salt privately made can be dispensed as the owner pleases, but only after paying the duty. [*Cf. Admin. Repts. Dept. Salt Rev.*, 1895-6 to 1904-5; *Dist. Gaz. Bellary*, 177-9; *Anantapur*, 127-8; *South Arcot*, 234-6; etc.]

PRODUCTION AND TRADE.—*Consumption and Taxation.*—"During the six years, 1898 to 1903, the average annual production of salt in India amounted to 979,572 statute tons." And following on the shrinkage of 1903, there was a great increase on production in 1904, viz. to 1,171,050 tons, in 1905 to 1,291,137 tons, and in 1906 to 1,225,280 statute tons (= 1,244,939 metric tons). This expansion was mainly in Bombay and Madras sea-salts. The output of the former in 1903 was 267,619 tons, in 1904 it expanded to 430,409 tons, but in 1905 became 425,090 tons, and in 1906, 390,535 tons; while in the latter (Madras) the production in 1903 was 244,923 tons, in 1904 it became 356,834 tons, in 1905, 388,646 tons, and in 1906, 412,717 tons. During the five years ending 1906-7 the Imports of salt have been:—1903-4, 446,559 tons; 1904-5, 486,980 tons; 1905-6, 464,531 tons; and 1906-7, 467,949 tons, valued at Rs. 66,77,390 (£445,159). The total supply may thus be obtained by adding together the production and imports; thus in 1903-4

it was 1,426,131 tons, and in 1904-5, 1,657,185 tons; hence home production in the former represented 68 per cent. and in the latter 70 per cent. of the consumption.

It is thus evident that the reductions of the duty on salt, made successively in March 1903 and March 1905, stimulated consumption; all the provinces except Bengal (which draws its supplies from Liverpool and Germany) have shown an increased consumption. From 1888 to 1903 the duty throughout the greater part of India was Rs. 2-8 a maund of 82½ lb., but in the latter year this was reduced to Rs. 2. Again, in March 1905, the general rate for India, except Burma, was reduced to Rs. 1½ per maund. A further reduction was made by the budget of March 1907, and "the tax is now levied at the uniform rate of one rupee per maund over practically the whole of India and Burma" (*Mor. and Mat. Prog. Ind.*, 1905-6, 75).

Custo s and Control.—It has been fully exemplified that in the production of salt in India there are two chief operations: (1) mining and (2) evaporation. Under the supervision of the various departments, preventive establishments are maintained, to guard against illicit traffic in salt removed from natural deposits; from manufactories, whether owned by Government or private persons; and from saltpetre refineries, etc. The traffic coastwise is also subject to supervision, and special measures have been undertaken to check smuggling from French and Portuguese, as also from Native State, territories. Briefly, however, the modern policy has been to work salt so economically and scientifically that the tax may assume the form of ordinary profit on production and be collected before delivery to the traders, so as to place its subsequent movement free of all restraint. This, when contrasted with the vexatious and expensive system inherited by the British administration, will be seen to be a vast improvement. Salt is readily available throughout the Empire, its price has been equalised, facilities of traffic increased, and a system of credit established. "At the present day, for example, a trader of the United Provinces wishing to obtain Sambhar salt has merely to deposit his money at the nearest treasury, sub-treasury, or appointed railway station or post-office, in order to receive his consignment without delay or trouble, at any railway station he chooses to name. In Madras the trade in salt is facilitated by a credit system, under which a merchant on depositing securities (with a slight margin for fluctuation of price) receives a six months' credit for payment of duty on which he can draw from time to time. A similar system, but with a shorter credit period, obtains in Bombay" (*Imp. Gaz.*, l.c. 252).

The following statement exhibits the imports from foreign countries and the production of salt within India in relation to consumption and revenue :—

—	Imports in Maunds.	Production in Maunds.	Total Supply in Maunds.
1890-1	10,790,319	28,649,890	39,440,209
1895-6	11,443,572	30,865,566	42,309,138
1900-1	9,810,587	27,363,449	37,174,036
1901-2	14,346,947	30,000,077	44,347,024
1902-3	11,835,449	28,316,479	40,151,928
1903-4	12,460,259	22,400,971	34,861,230
1904-5	13,301,600	30,058,737	43,360,337

To contrast with these figures and to show the quantity consumed and the gross revenue realised, the following table may now be given :—

Consumption.

—	Quantity in Maunds Consumed.	Duty in Rs. Realised.
1875-6	24,237,730	5,88,09,810
1880-1	27,363,609	6,76,64,790
1885-6	31,690,062	6,02,48,710
1890-1	33,280,738	7,98,10,730
1895-6	34,686,981	8,31,14,370
1900-1	35,815,282	8,75,57,786
1904-5	39,377,566	7,60,28,401
1905-6	40,729,000	6,05,55,000

These tables show the share of the salt of India that is drawn from foreign countries—approximately a little over one-third the annual supply—the quantity passed into consumption, and the duty realised therefrom. In 1875-6 the consumption was 24½ million maunds, in 1904-5 it had expanded to 39½ million maunds, and in 1905-6 to 40½ million maunds. The consumption steadily progressed and was little, if at all, affected by the fluctuations in the rate of duty charged. But during the years 1904-6, while the duty declined materially the consumption made a record expansion. And it may be added that more recent forecasts would seem to show that the increase may soon compensate for the reduction in rate of revenue. The demand for salt would doubtless decrease in the affected areas, and yet a study of the figures of salt consumption by themselves for the whole of India during the past thirty-five to forty years give no sort of indication of the years of famine included within that period. The progression has kept pace with the increase in population, and has been little if at all affected either by famine or taxation. If surrendered to private enterprise the price all over India would rise and become unequal, thus leading to numerous difficulties and hardships. Thus it may be said salt is administered on a commercial basis and the profit secured returns in lessened taxation.

Increasing Demand.

Duty Reduced.

No Indication of Famine.

Increased wth Population.

Successful Administration.

The returns of the salt trade manifest a continuous expansion with periods of sudden development rather than of shrinkage. Thus, for example, in 1878-9 the consumption was 25½ million maunds and in the next year it became close on 28 million. So again, in 1883-4, the consumption was a little over 30½ million maunds, and in 1884-5 it became 33 million maunds. In only two years are material shrinkages manifested, viz. 1885-6 and 1888-9, yet in these the effect was only temporary and did not in any way disturb the steady advancement. It is well known that seasons of deficient supply occur from climatic conditions retarding production, and the years 1885-6 and 1888-9 are likely to have been of that nature. At the present time salt sells on an average at one halfpenny a pound throughout the greater part of India, and still produces a net revenue of 5 to 6 million pounds sterling. The incidence of the tax prior to 1903 was 4-9 annas per head of population, and by recent enactments it became only 4 annas (4 pence a head), the sole contribution of a large percentage of the people to the administration.

Sudden Expansions.

Deficient Supply.

Incidence of Tax.

Uses.—It is needless to enumerate the numerous purposes served by salt. It is used as an article of food, as a manure, in fish-curing (see p. 546), vinegar purification (see p. 1111), etc., etc.

ALTP TR, NIT OR P TA IU NITRAT : Ball, *Man. Econ. Geol. Ind.*, iii., 499-501; Watt, *Agri. Ledg.*, 1902, No. 5, 111-4; Holland, *Rev. Min. Prod. Ind.*, 1898-1903, in *Rec. Geol. Surv. Ind.*, 1905, xxxii., 86-90; also *Rev. Min. Prod. Ind.*, 1906, xxxvi., 81; Hooper, *Repts. Labor. Ind. Mus.*, 1902-3, 23-4; 1903-4, 37; also *Agri. Ledg.*, 1905, No. 3. The term Saltpetre is used to designate nitrates found in a natural state in many parts of the world, chiefly South America, Spain, Persia, Hungary and India. In the last-mentioned country the salt bears the following vernacular names :—*suriakhar*, *shóra* (*sórá*), *potti-luppu*, *veti-uppa*, *sandawa*, *yánzin*, etc. *Shóra* is its Persian name Sanskritised into *soráka*.

Occurrence.—According to Holland, the necessary conditions for the formation of saltpetre in a soil are—“(1) supplies of nitrogenous organic matter; (2) climatic conditions favourable to the growth and action of Winogradsky’s so-called nitroso- and nitro-bacteria, converting urea and ammonia successively into nitrous and nitric acids; (3) the presence of potash; and (4) meteorological conditions suitable for the efflorescence of the potassium nitrate at the surface.”

The necessary combination of characters is to be found in a marked degree in various districts in the Indo-Gangetic tract, especially in the Bihar section, chiefly Gaya, Tirhut, Saran and Champáran. “In this part of India we have a population of over 500 per square mile, mainly agricultural in occupation, and thus accompanied by a high proportion of domestic animals, supplying an abundance of organic nitrogen. With a mean temperature of 78° F., confined to an annual range of 68°, and for a large part of the year, when the air has a humidity of over 80 per cent., with a diurnal range not exceeding 8° above or below 84° F., the conditions are unusually favourable for the growth of the so-called ‘nitrifying’ bacteria.”

“With a population largely using wood and cow-dung for fuel, the soil around villages naturally would be well stocked with potash; and finally, with a period of continuous surface desiccation following a small rainfall, the subsoil water, brought to the surface by capillary action in the soil, leaves an efflorescence of salts, in which, not surprisingly, potassium nitrate is conspicuous. Under these conditions Bihar has for many years yielded some 20,000 tons of saltpetre a year” (Holland, *l.c.* 86-7). To a less extent, commercial saltpetre is also obtained in the United Provinces (*e.g.* Cawnpore, Ghazipur, Allahábád, Benáres), the Panjáb, Kashmir, Central India (Bhind and Jwargarh), Bombay, Madras (Coimbatore, Salem, Kistna, Vellore, Trichinopoly, Madura), and lastly Burma (Tenasserim).

Manufacture.—Hooper has furnished a concise account of this subject. In preparing crude saltpetre from nitrous earth there are two distinct processes—(1) the leaching or exhaustion of the saline matter by allowing water to percolate through the nitrous earth; (2) the evaporation of the liquor so obtained either by the sun’s rays or by artificial heat. These processes are carried on in Bengal by a special caste of men, the *luniaks* or *nunias*, but in parts of the United Provinces and the Panjáb, ordinary villagers of no special caste engage in the industry. Near Hissar, the crude-nitre makers are generally low-caste *kumbhars*, or other Hindus or Mussulmans. The nitrous earth is collected from November to the commencement of the monsoon. The surface of the soil is scraped off to a depth of half to one inch and the earth made into heaps or taken to the factory.

In a factory examined at Murwanpur, four miles from Cawnpore, the following was the process of manufacture :—" The earth is stacked by the side of two oblong pits or filters (*kuria* or *kothi*), 7 feet long, 3 feet broad, and 1 foot deep. They are placed end to end with an earthen *ghara* or jar (*nand*), 1½ feet in diameter, buried in the ground between them. The floor of the filter is made of puddled clay, and is so arranged that the slope on either side is towards the central longitudinal line of the filter. This central line has a slope towards the outlet connecting with the jar. On the floor is laid a framework of small brushwood the sides of which rest on the clay, and the cross-pieces of which are laid on top of the side-pieces. The filter is carefully packed with the nitrous earth, and water then poured on the surface, which commences to trickle out in one hour or so as nitrous brine. After the first charge of water, more is poured on the surface until the brine trickling out appears to be too weak to work. The exhausted soil from the filters is then taken out and thrown on a heap, which gets large by the time the season ends. The liquid from the *nand* is baled out and transferred to an iron evaporating pan or boiler (*karahi*), which is supported on a brick fireplace. The boiler is 5 feet in diameter and is made up of iron sheets riveted together, and costs about Rs. 20; the liquor is boiled for about seven hours or until it is sufficiently concentrated. To determine this a drop of the solution is taken and placed on the thumb-nail. If crystals appear at once, the boiling is considered to be complete.

Filters.

Nitrous Brine.

Boiler.

"The hot boiled liquid is transferred to open vessels of rough pottery to cool and crystallise. The crystals will usually have sufficiently formed to be collected next morning. They are taken out and drained in baskets which act as filters, and then thrown into a pit in the ground, where the crude saltpetre, or *kachcha shora* as it is called, is stored" (Hooper, *l.c.* 26-7).

Crystals.

Saltpetre thus obtained (by artificial heat) is termed *jaria shora*. The method of making crude saltpetre by the heat of the sun is practised in the drier parts of the Panjáb and in other provinces where the climate permits, but the saltpetre (*abi shora*) is not considered of such good quality. A large quantity of *abi shora* is made annually at Hansi in the Hissar district.

*Jaria Shora.**Abi Shora.*

"The quality of crude saltpetre is considerably influenced by the quality of the nitrous earth from which it is made and the processes adopted for its manufacture." Analyses of various samples of crude saltpetre are given by Hooper (*l.c.* 31-2). The amount of potassium nitrate ranges from nearly 80 per cent. in a sample from Hamerpur, to as low as 26·8 per cent. in a sample from Okara, and an average of 53 might be given.

Yield.

Impurities.—The chief impurity is common salt. Ordinary samples of crude nitre are stated to contain from 40 to 64 per cent. nitrate of potash, and to be worth, at manufactories within easy distance of railways in the north of India, one anna per unit per maund for the percentage of potassium nitrate present. According to Hooper, a sample containing 40 per cent. nitrate of potash would thus be worth Rs. 2-8 per maund, and samples containing 64 per cent. of nitre, Rs. 4 per maund. Samples with less than 40 per cent. nitre would be valued at less, and those containing over 64 per cent. nitre at more than one anna per unit.

Impurities.
Common Salt.

Price.

Refining.—Before the nitre is ready for market, it has to be freed from impurities. This is done in refineries, of which there were 399 at work in Northern India (Panjáb, North-West Frontier Provinces, United Provinces, Bihar) in 1904-5; 281 of these were in Bihar (*Rec. Geol. Surv. Ind.*, 1906, xxxiii., 19). Hooper gives a full account of the arrangements in a refinery at Jaimow, Cawnpore, in the United Provinces, to which the reader is referred for details. With regard to the methods followed, he says, "The process varies in different refineries and in different parts of the country. But as chloride of sodium is the principal impurity and as its solubility is practically constant, all the processes followed are based on the varying solubility of nitrate of potassium in hot and cold solutions."

Refineries.

Location.

The method pursued, according to Hooper, is essentially as follows:—In starting the refining process, nitre earth, obtained from the factory soil, is filtered and the crude nitre solution obtained boiled down, clarified by sedimentation

and set out to crystallise. "In from six to ten days the crystals are extracted and the residual *tor* or mother-liquor is then available for future use." In this mother-liquor, crude saltpetre is dissolved and the solution concentrated by boiling in large evaporating-pans. During the boiling a dirty white granular substance (*sitta*) falls to the bottom of the pan and is removed as it forms. This *sitta* is sometimes washed and the washing returned to the pan. In Bihar it is mixed with the refinery earth. "It is composed for the greater part of common salt mixed with other salts, earth and nitrogenous matter." Meanwhile the evaporation of the liquid in the pan is continued at the temperature of boiling water. The scum which forms on the surface (*zag, zoga, mail* or *phain*) may be removed at this stage or after transfer to the settling-tank. "After boiling for three hours, or until the liquid changes from a dark to a light yellow colour, the concentration is considered complete." The clarified liquor is transferred into one or more crystallising vats. "At the bottom of the settling-tanks is found a substance called *matiaree*, which is a by-product containing nitrates, and is accordingly carried off and mixed with the nitrous earth in the factory yard. The crystallising-vats under the sheds are filled with nitre liquor to about six inches from the top. In the United Provinces, on the surface of each is floated a trellis-work made of interlaced bamboo sticks (called *tattis* in Cawnpore). This device facilitates the formation of good crystals. After seven days the bamboo frames are removed and the adhering nitre crystals are shaken or picked off, and the crystals at the bottom and sides of the trough collected in a heap and drained."

"The damp saltpetre is contaminated with the mother-liquor adhering to it and minute crystals of salt, and these must be removed by washing before the salt is ready for market." "Bags containing the refined substance are placed over an empty tub or vat, which is slightly tilted to allow the liquor to drain. Cold water is sprinkled from time to time upon the saltpetre through the open mouth of each bag. This water trickles slowly through the saltpetre crystals, carrying with it inferior salts in solution. Some saltpetre is also dissolved, but the loss is not great. After the washing, the refined saltpetre is spread out and dried, and after remaining a few hours, is conveyed to the store godown" (Hooper, *l.c.* 36). The price of refined nitre in 1904 is stated to have been Rs. 5-8 to Rs. 6 per maund in Bihar and Hissar, Rs. 8 in Cawnpore, and that of extra good quality, Rs. 9.

Price.

Uses.

Gunpowder.

Dyeing.
Medicine.

Manure.

Uses.—It is even still an important ingredient in gunpowder, owing to the large volume of oxygen it contains, the ease with which it parts with its oxygen, and the fact that it does not readily absorb moisture from the air. On the other hand, sodium nitrate is preferred for the manufacture of nitric acid because it is cheaper and yields about 7 per cent. more acid. In India, saltpetre is used in association with certain animal dyes, such as lac and cochineal. In MEDICINE it is sometimes prescribed because of its diaphoretic properties. Its merits as an anti-septic in preserving fish and meat are well known. As a MANURE it is much appreciated, especially for wheat and tobacco (see p. 771; also *c.f. Agri. Ledg.*, 1893, No. 10; 1897, No. 8, 171), and in India it is sometimes used as a flux in glass-making.

Production.

Production and Trade.—According to Holland, the returns are so imperfect, being considerably below the amounts of export, that these must be taken as the only satisfactory index of the extent of production. For the period which he reviews (1897-1903), the average annual exports, including those across the frontier, amounted to 382,353 cwt., valued at £262,592. He further states that a comparison with the figures returned for the past twenty years shows that there has been only a slight reduction in the amount exported, in spite of the discovery of large deposits of sodium nitrate (now being extensively utilised in America), of variations in tariff, and of wholesale changes in the substances used for manures and in the manufacture of explosives. For the six years 1878-1883 the average quantity of

Trade.

saltpetre exported amounted to 405,568 cwt. a year, whilst for a similar period ten years later, 1888-1893, the average annual exports were 389,989 cwt. The highest values, ranging from £600,000 to nearly £900,000, occurred at the time of the American Civil War from 1860 to 1864, but saltpetre was then an essential constituent of explosives and India had almost a monopoly of supplies.

The actual figures of the exports of saltpetre during the five years ending 1906-7 were as follows:—1902-3, 410,622 cwt., valued at Rs. 43,27,283; 1903-4, 392,114 cwt., valued at Rs. 40,75,364; 1904-5, 348,741 cwt., valued at Rs. 36,23,823; 1905-6, 336,429 cwt., valued at Rs. 38,52,919; and 1906-7, 353,378 cwt., valued at Rs. 41,42,527 (= £276,168). In the last year the largest quantities were distributed as follows:—United States, 105,034 cwt.; United Kingdom, 98,804 cwt.; China (Hongkong), 78,499 cwt.; Mauritius, 26,174 cwt.; etc. Practically the whole of the exports go from Bengal (348,263 cwt. in 1906-7). Holland (*Rev. Min. Prod.*, in *Rec. Geol. Surv. Ind.*, 1907, xxxvi., 81) shows the average value per cwt. for the past five years as 14·5 shillings, and he points out that the importance of the industry may be inferred from the fact that in Bihar (during 1906) there were 50,469 workers employed.

Recent Exports.

Only very small quantities are imported into India by sea, averaging about 19 cwt. during 1901-5, but in 1905-6 the quantity suddenly rose to 4,848 cwt. (owing to the importation into Bengal of 4,820 cwt. from China), and in 1906-7 fell to 28 cwt. Considerable quantities, however, are annually carried across the frontier, almost entirely from Nepal. The actual figures of Trans-frontier imports for the period 1900-5 were as follows:—1900-1, 4,590 cwt.; 1901-2, 11,352 cwt.; 1902-3, 2,758 cwt.; 1903-4, 4,429 cwt.; 1904-5, 2,872 cwt.

D. P., vi., pt. ii., 480-1. Bowstring Hemp.

A stemless bush with a rosette of succulent radical leaves, each ending in a long spine. It is by some persons held to be indigenous to India, by others, like the remaining members of the genus, to be African. But if not a native of India, the vernacular name *murva* must have been adapted to it from some other plant which in ancient times afforded the *maurvi* string of the warrior caste (*Institutes of Manu*, ii., 42, 44). One or two species are fairly extensively grown in Indian gardens as ornamental shrubs, and here and there occasionally raised on account of the fibre. From the succulent leaves, the fibre is extracted and is much valued, because of its elasticity and consequent suitability for bowstrings. The reader will find much useful information, on this subject in *The Agricultural Ledger* (1896, No. 30), where it will be found *murva* fibre has been recommended as a catch crop with tea. [*Cf. Roxburgh, Obs. on Substitutes for Hemp and Flax*, 1801, No. 12; Dodge, *Useful Fibre Plants of the World*, 1897,

The Sandal-wood, known in Indian vernaculars as *chandana*, *chandal*, *sandal*, *sukhad*, *gandha*, *gandada*, *suket*, *sukhud*, *sundel*, *srigandam*, *santagu*, etc., etc. A small evergreen tree met with in the dry regions of South India (Mysore, Coorg, South Maráthá, Hyderabad, Karnátak, the Western Ghats, Nilgiri hills, Coimbatore), and in North India chiefly as a cultivated plant. It affects open forest lands with grass and patches of other trees, usually frequenting red or stony soils. It is a root parasite on a long series of host plants, and hence apparently the difficulties experienced in systematic plantations where provision has not been made for this requirement. On rich soil the plant grows well, but the wood is deficient in odour, consequently inferior commercially.

Parasitism.

History.—Sandal-wood has been known in India from the most ancient of classic times, the Sanskrit authors distinguishing various woods according to colour. *Chandana* might be spoken of as the collective name for the series, *srikhanda* the true (or white sandal), and *pitachandana* the inferior (or yellow sandal), both being derived from *Santatum album*. They distinguish two kinds of red sandal or *raktachandana*, namely *Pterocarpus santalinus* (see p. 909) and *Cesatpinia sappan* (see p. 194). So, in a like manner, these various woods were known to the early Arab traders who visited India and China. Avicenna (ii., 2, 649) gives the medicinal properties of the true sandal. Serapion (*De Simpl.*, 346) describes white, yellow and red sandal, and speaks of the finest qualities coming from Sini (China), an opinion doubtless due to the well-established circumstance that the traders from China were in the habit of treating India as a half-way house and exchanged some of their Chinese wares for Indian products and manufactures, and on arrival at Arabia all the goods ultimately disposed of came to be spoken of as Chinese, because of the traders having come from China, just as in the further distribution of these self-same wares they received the names of the coast towns of Arabia from which they were finally distributed to Egypt and Europe. [*Cf. Paulus Ægineta* (Adams, transl. and Comment.), 1847, iii., 448-9.]

Marco Polo, in the 13th century, makes frequent reference to Red Sanders Wood and to Sandal-wood, and Garcia de Orta (*Coll.*, xlix.) says the white and yellow kinds grow in Timor, where it is called *chundana* and by the Arabs *sandal*, and the other kinds in the Malaya Islands, a special red form known as *vermelho* being obtained in Tenasserim. [*Cf.* with recent information regarding *kalamet* (*Mansonia Gagei*), *Journ. Linn. Soc.*, 1905, xxxvii., 250-62.] Sandal is described by Acosta, Linschoten, Pyard, Matthioli, Bontius, Hove, etc., and for Indian writers consult the following:—Abul Fazl, *Ain-i-Akbari* (Blochmann, transl.), i., 81; Jahangir, *Memoirs* (Price, transl.), 14, 63; Foster, *E.I.C. Letters*, 1617, v., 267; vi., 163, 170; Alexander Hamilton, *New Acc. E. Ind.*, 1727, i., 306; Jones, *Sel. Ind. Pl.*, As. Res., iv., 253; Milburn, *Or. Comm.*, i., 291; Rama Rao, *Ind. For.*, 1908, xxxiv., 17-21.

Cultivation.—John Scott, Curator of the Royal Botanic Gardens, Calcutta, showed that sandal-wood was a root parasite on many plants (*Journ. Agri-Hort. Soc. Ind.*, 1871, ii., 287). Barber (*Ind. For.*, 1902, xxviii., 340) urged that a careful study of this circumstance might lead to much-needed reforms in the methods of cultivation, as also to the true explanation of the peculiar disease known as "Spike." Brandis followed this up by a review of the literature on the parasitism of sandal (*Ind. For.*, 1903, xxix., 3-6). Rama Rao (*Ind. For.*, xxix., 386-9) has furnished full details of the parasitism, also excellent illustrations, and given a list of some 100 host plants upon which the sandal had been found. Lastly,

Barber contributed a further paper (*Ind. For.*, 1904, xxx., 545-8; 1905, xxxi., 189-201), which supplies details of his microscopic studies of the haustoria and their preferences for certain hosts. Lushington (*Ind. For.*, 1902, xxviii., 139-40), Rama Rao (*l.c.*, 1904, xxx., 248-67, 357-62, 397-402) and other officers of the Forest Department have also devoted much careful study to the cultivation of sandal, more especially in relation to the production of the maximum percentage of rich-scented wood. Lushington observes: "On the whole I am inclined to think that the best way of aiding the reproduction of sandal-wood artificially is to increase the scrub, and this is best effected by merely keeping out fire and grazing. As soon as the scrub reaches two or three feet, sandal reproduces naturally from seed dropped by birds, and this may perhaps be further assisted by dibbling." Rama Rao urges that weeding is dangerous, and that only surface pruning when the scrub becomes too dense should be indulged in. Lushington mentions 8 inches growth in girth per ten years as a safe average, and the exploitable age of the trees as forty years, the minimum size being then 32 inches at 4½ feet from the ground.

Natural

Exploitable Age.

DISEASE OF THE SANDAL.—In 1892 attention was drawn to the appearance of a disease among the sandal-trees which was attributed to borer beetle (Lehmann, *Ind. For.*, 1901, xxvii., 97). Stebbing (*Ind. For.*, 1903, xxix., app.) furnished a useful account of the insect enemies of the plant. In the *Forest Administration Report of Coorg for 1903* it was stated that 20,800 diseased trees had been uprooted. Similar reports exist regarding other districts, while many writers affirm that the extermination of affected trees has not checked the spread of the disease. Mr. McCarthy, Deputy Conservator of Forests, would appear to have been the officer who first recorded the disease, and who apparently gave it the name "Spike." The diseased branches seem to shoot up, forming narrow, thick, stiff leaves, reduced in size as the disease advances. The disease spreads to branch after branch, no flowers are formed, and finally the tree dies. Both Butler and Barber have examined with care diseased trees, but have failed to discover a fungus or other micro-organism present in or upon the diseased tissues. The roots of diseased trees have been traced from the stem to their ultimate fibrils, and, long before their parasitic haustoria were reached, these roots were very frequently found dead. Butler suggested that the disease somewhat resembled "Peach yellows," and, acting upon this idea, experiments were performed to test whether it could be communicated by budding. This was found impossible. It would thus seem that as yet no satisfactory explanation of the disease has been ascertained, but most officers appear to consider that it proceeds from imperfect nourishment due to the insufficiency or unsuitability of the associated plants upon which sandal-wood is parasitic.

Diseases.

"Spike."

Imperfect
Nourishment.

Sandal-wood Oil and Perfume.—It is a somewhat surprising circumstance to learn that in the region of greatest success in sandal-wood production the manufacture of the oil has hitherto proved a failure financially, and is only practised on a small scale and by a very inferior process (Holmes, *Pharmaceut. Journ.*, 1885-6, 3rd ser., xvi., 819-22; Sawyer, *Odorography*, i., 315). As matters stand, the sandal-wood oil of India is mainly, if not entirely, produced at Kanauj in Oudh.

Oil

Kanauj in
Oudh.

From official correspondence it is learned that according to Mr. S. Ali Hussain, sandal-wood oil was formerly distilled by several firms in Lucknow and Jaunpur, where the preparation of sweet-scented essences is a recognised industry. For some years past the industry in these towns has declined, and it has become the practice to purchase the oil from Kanauj. The method of preparation described by the Lucknow and Jaunpur men was as follows:—Two kinds of sandal-wood, red and white, are known in these provinces. The former is used medicinally and in dyeing, while the latter alone is employed for the extraction of the oil. Trees are found here and there growing in the provinces, but good wood can alone be obtained from the Bahraich forests. Until the last ten years wood from

Wood Imported.	these forests was used largely, but latterly (owing to the low yield obtained from the local wood) supplies have been imported from Bombay which are believed to have been derived from Mysore and Malabar. The best wood for the perfume trade is held to be that from the damper tracts of the latter—it being assumed that the proportion of oil present depends on both the dampness of soil and climate of the country of production.
Operations.	The wood is first reduced to a powder, about 40 to 60 lb. of which are soaked in clean water for 48 hours, then placed in a copper still. The water, carrying the oil evaporates and is condensed in the usual way, when, on cooling, the oil floats on the surface and can be collected. It is then refined in various ways—filtered, or kept for a year until the sediment of impurities has settled at the bottom, etc. It is believed that the water has an important function to perform, since certain waters are superior to others. Kanauj is supposed to soften the wood and facilitate the liberation of the oil, while that of Jaunpur improves the quality of the oil. The Kanauj manufacturers, however, attribute their success to their skill and not to any special property possessed by the water.
Peculiar Waters.	It is said that the yield in Kanauj is about 2½ to 3 seers of oil to one maund of wood. The oil that comes off first from the still is the best quality. The following rules are recognised by the manufacturers:—(1) the heat must be uniform; (2) the receivers must be removed directly they are full; (3) cleanliness is essential. If the tinning of the interior of the still is worn out, the oil gets greenish in colour from copper; (4) all joints must be steam-proof.
Yield.	There are various qualities of the oil—that made at Kanauj is called <i>malleagiri</i> ; inferior kinds are <i>kathia wala</i> and <i>jahazi</i> . But the inferior oils are believed not to be made at Kanauj, and to be used by the traders for adulteration. The annual outturn at Kanauj is about 100 maunds of the oil; but the production is said to be declining, the reason given being the increasing price of good wood, which now fetches Rs. 30 to Rs. 35 a maund. The scarcity of fuel is given as another reason of the decline, and the adulterations practised by the dealers as a third reason. Ordinary quality of Kanauj oil sells at about Rs. 17 a seer (= 2 lb.). [Cf. Foster, <i>E.I.C. Letters</i> , 1617, v., 339; Gildemeister and Hoffmann, <i>Volatile Oils</i> , 1900, 338–45; <i>Pharmacog. Ind.</i> , iii., 232–4; Hare, Caspari and Rusby, <i>National Stand. Dispens.</i> , U.S.A., 1905, 1104–5; Hooper, <i>Rept. Labor. Ind. Mus.</i> , 1903–4, 27.]
Observances.	
Qualities.	
Adulteration.	
Price.	
Trade.	Trade. —The sandal-wood of Mysore and Coorg has not only been known from the most ancient times, but has ranked as the finest quality for centuries. It is somewhat surprising, however, to read in Stein (<i>Ancient Khotan</i> , 447, 452) of a comb found at the Kara-dong ruins (8th century) said to be made of sandal-wood. If that determination be correct it would point to an Indian trans-frontier traffic of a more varied and extensive kind than hitherto contemplated, as existing at that early period. The Indian supply of the true sandal-wood is drawn from Southern and Western India, and there is nothing to show that this was not always the case. The earliest European writers on the modern traffic refer to the sandal of Macassar, and a supply from there is still recognised in the markets of the world. A third grade is designated West Indian, though it is in reality procured from Venezuela. According to Gamble, the average annual sales of Mysore amount to 1,841 tons; Coorg, 102 tons; Madras Presidency, 75 tons; and the Bombay sales a still smaller quantity—or, say, a total annual output of 2,000 tons, valued at £40,000. Speaking of Mysore, Pigot (<i>Mysore Sandal-wood</i> , 1899) says the wood is found in a continuous belt, about 240 miles long by 16 broad, running from the north-west to the south-west of the province. A second and much smaller and less important zone lies farther to the east. The total area of both belts is about 5,450 square miles. This, therefore, is the chief sandal area of the world, since Mysore produces about seven-eighths of the total annual supply. Pigot classifies the grades and materials into some eighteen sections, ranging in size from billets not less than 20 lb. in weight (<i>vilayat budh</i>), the finest grade, down to the sawdust obtained in sawing up the

oap-nut.

The former is the Soap-nut tree of Northern India and the latter of Central, Western and Southern India. They are collectively described by the Natives of India under the vernacular name *ritha*, and in Sanskrit by the names *phenila* and *urista*. Other vernacular names are, however, used, such as *rithia*, *rita*, *aritha*, *dodan*, *kanmar*, *itā*, *ud-rak*, *prounanga*, *puvandi*, *kunkudu*, *thali*, *thalay*, *chana*, etc. The fruits of the North Indian form come into market about January or February, and of the South Indian a little later, say about March to April. From time immemorial these "nuts," or, rather, dried fleshy berries, have been employed as detergents, and by the dyers of India are supposed to possess special merits as a preparation (if not mordant) for certain dyes. In Kashmir the soap-nut is preferred for washing shawls to European soaps. In other parts of the country they are specially valued for washing silk, and by the Indian jewellers are resorted to for the restoration and brightening of the silveriness of plate and ornaments tarnished by exposure.

Fruit.
Seasons.

Detergent.

As one of the many curious uses of these nuts, it may be said that they are sometimes employed in washing and bleaching cardamoms, and are supposed not only to improve the colour but also the flavour of the spice (see p. 515). The soap-nut is used medicinally, both by the Hindus and Muhammadans, and its properties are detailed in the *Makhzan-el-Adwiya* and the *Taleef-Sherief*. More up-to-date details will be found in the *Pharmacographia Indica* (i., 367-70), and in the *Materia Medica of Madras*, by Moodeen Sheriff (112-4), etc., etc. Mr. A. Storey of Oodeypore pointed out that the honey of the flowers of these trees was poisonous to bees (*Journ. Bomb. Nat. Hist. Soc.*, 1890, v., 423). The soap-nut is much used in China for the same purpose as in India (Hosie, *Prov. of Ssu'ch'uan*, 1904, No. 5, 31).

Washing
Cardamoms.

Poisonous to
Bees.

Quillai Bark (the bark of *Quillaja saponaria*; *Kew Bull.*, 1904, 1-4) is sent to Europe from Chili as a soap substitute, and a demand has arisen for the same, which suggests the possibility of a foreign trade in the Indian soap-nuts—the above species—as also the pods of *Acacia concinna* (see p. 14).

Quillai Bark.

Chinese
Tallow-
tree.

The plant is easily raised from seed, but is usually propagated by layers or cuttings. The fruit is a 3-celled capsule, each cell with a single seed, surrounded with a thick greasy substance—the so-called vegetable TALLOW. In China this is used in place of animal tallow for the manufacture of candles and soap, also in dressing cloth. In addition to the solid fat, the seed-kernel yields about 50 per

cent. of a brownish-yellow OIL, which is employed medicinally, also as a burning-oil and in the preparation of umbrella varnish. Efforts have been made to utilise the tallow in India, but the labour and expense involved in extraction are said to be far in excess of the value of the product. In the *Annual Report* (1901-2) of the Industrial Section, Indian Museum, mention is made of a sample of kernels obtained from Kangra Valley which contained 63.6 of fat. Gamble says "experiments have been made by Babu Birbal at Dehra Dun and the wax was extracted and made into cakes, but the process was tedious and the result not very satisfactory, so that the culture of the tree for wax is not recommended." Further details regarding the manufacture, chemistry and trade in vegetable tallow will be found in *The Agricultural Ledger*. The leaves afford a black DYE about which little is known. The WOOD is white and moderately hard. It is made into bedsteads, tables, toys, and has been suggested as suitable for printing-blocks. [*Cf. Braunt, Pract. Treat. on Anim. and Veg. Costus.

AU UR A LAPPA, C. B. Clarke; Fl. Br. Ind., iii., 376;

COMPOSITÆ. The Costus, *kút*, *pachak*, *post-khai*, *rusta*, *ouplate*, *kostum*, *changala*, *sepuddy*, etc. A tall, stout herb, indigenous to the moist, open slopes surrounding the valley of Kashmir, at an elevation of 8,000 to 9,000 feet, and found also in parts of the basins of the Chenab and Jhelum, at 10,000 to 13,000 feet.

Early Records.

Costus root has been held in high repute as a medicine from remote times, but its origin was for long obscure and was erroneously referred to *Costus speciosus*. As with many other articles of merchandise, it came to be spoken of as obtained from regions that were only emporia, not localities of production. Thus Garcia de Orta (1563, *Coll.*, xvii.) states that it grows in the region between Bengal, Delhi and Cambay, and comes also from Chitore, whence it is brought to Cambay and Ahmalábád and exported to Europe and parts of Africa. The roots are actually dug up in large quantities in Kashmir, cut into small pieces and sent to Calcutta and Bombay, whence the drug is exported chiefly to China and the Red Sea. In Kashmir its collection is a State monopoly. Lawrence (*Valley of Kashmir*, 1895, 77) says: "Every year a large amount of the roots of the *Saussurea Lappa* is demanded by the State, and the villagers are obliged to bring a certain weight, for which they receive Rs. 4 per *kharwár* from the State. The root, which is known as *chob-i-kot*, is exported to India, and at present the monopoly in *chob-i-kot* is farmed out to a contractor for Rs. 45,000 per annum."

Kashmir.

State Demands.

Perfume.
Medicine.

Protection from
Moths.

In addition to its medicinal properties it is a valuable perfume and largely used in China as an incense. Is also said to be a good hairwash, having the reputation of turning grey hair black. In Kashmir it is much employed by shawl-merchants to protect their fabrics from moths and other insects. The absence of this particular perfume was for some time made the test for imitation shawls. [*Cf. Clusius, Hist. Exot. Pl.*, 1605, 204-6; *Pharmacog. Ind.*, ii., 296-303; iii., 165, app.; Henry, *Econ. Bot. China*, 1893, 19; *Rept. Ind. Hemp Drugs Comm.*, 1894, iii., 94; *Ann. Rept. Ind. Recent investigations have shown, however, that the tree does occur in Bengal (especially Chota Nagpur), though not in Assam.

Oil.

The most valuable product of this tree is the OIL yielded by the seeds, which is used for culinary and lighting purposes, also as a hair-oil and in Native medicine.

THE MARKING-NUT TREE

A U
I ICU
Gingelly

It is said to be an efficient agent for cleaning and promoting the growth of the hair, and is reputed to be the original Macassar oil. Recently there has been a considerable demand from abroad for the seeds (Hooper, *Agr. Ledg.*, 1905, No. 1). A large quantity of seed was found to be available in India, but owing to its being edible, jungle tribes would, in times of scarcity, gather the fruits for their own consumption rather than for trade purposes. It is also said that none of the oil is sold or exported in any of the districts specially investigated. The tree is noteworthy from its being one of the most highly valued plants of the Lac insect. As a lac-yielding tree it is especially prevalent in Raipur and Bilaspur in the Central Provinces. The Wood is hard, strong and durable and used for making pestles, cart-wheels, axles, ploughs; also for rollers of sugar-mills, and of cotton and oil presses. [*Cf. Pharmacog. Ind.*, iii., app., 138-9; *Journ. Soc. Chem. Indust.*, 1900, xix., 254, 672; Thorpe, *Dict. Appl. Chem.*, 1900, iii., 31; Wright and Mitchell, *Oils, Fats, etc.*, 1903, 542; Hooper, *Rept. Labor. vi., pt. ii.,
498-500.
Marking-
nut.

It yields by tapping the stem an acrid, viscid juice from which a varnish is made (see *elanorrhœa*, p. 779), but the most important product of the tree is the fruit, the pericarp of which contains a bitter and powerful astringent principle, universally used in India as a substitute for marking-ink. It gives a black colour to cotton fabrics, but before application must be mixed with limewater as a mordant. In parts of Bengal the fruits are also used as a dye, either alone or with alum, while throughout India they hold an important place in Native medicine. The fleshy cups on which the fruit rests, and the kernels of the nuts, are eaten as food. [*Cf. Acosta, Tract. de las Drogas*, 1578, 323; Piso, *De Med. Bras.*, 1648, 57-9; also *Mant. esame.

story.—Botanical evidence alone might lead to the supposition that the *Sesamum* of sub-tropical agriculture was originally a native of Africa, in which continent there are some eight or nine truly wild forms, and where the present species is known to have been cultivated from remote times. De Candolle is of opinion that the plant was introduced into India from the Sunda Isles at a period prior to the Aryan invasion. "Rumphius," he says, "gives three names for

the sesame in three islands, very different one from the other and from the Sanskrit word, which supports the theory of a more ancient existence in the Archipelago than on the continent of India." He also adduces the fact that a plant found wild on the mountains of Java was determined to be *S. indicum*. If this were so, however, we might expect to discover some trace of the Sunda name in the languages of India. Instead we find a singular uniformity throughout the most diversified tongues in the names for the plant, its seed, and oil, which are clearly of unmixed Sanskrit origin. Moreover, the name enters into the early primitive conceptions of domestic life and religious ceremonial, and even assumes a generic from a specific significance, becoming "oil" (*taila*) in more recent times on the discovery of other oil-yielding plants. Sesamum is frequently mentioned by the Greek and Latin authors. Indeed some of the Indian names given to it come from Arabic or Persian; few or none belong to the aboriginal languages of India. In this connection may be mentioned the names *gingeli*, *gergelim*, and *jinjili* or *jinjali*, which Dr. Rice derives from the Arabic *chul-chulan*, and Yule and Burnell from the Arabic *al juljulan*. There is, moreover, no reason to doubt that the *tila* of the Sanskrit authors is the *til* of India to-day (Dutt, *Mat. Med. Hind.*, 216-7).

Though sesamum has not hitherto been recorded as found wild in any of the warmer tracts of Central Asia, it is cultivated everywhere in the Himalaya, in Afghanistan, Persia, Arabia and Egypt. There would, therefore, seem little evidence opposed to the statement that, if not originally native of the warm temperate tracts of India, it was probably brought to India before it found its way to Egypt and Europe. But it is certainly very remarkable that few, if any, of the early European travellers in India, such as Garcia de Orta, Linschoten, etc., etc., make mention of this plant or of its oil. In the *Ain-i-Akbari* (1590) frequent reference is, however, made to both the black and the white-seeded forms, so that there is abundant evidence of its having been an important crop in India for at least the past 300 years. [*Cf. Paulus Aegineta* (Adams, transl.), 1847, iii., 331; Varthema, *Travels* (ed. Hakl. Soc.), 86-7; Camerarius, *Hort. Med. et Phil.*, 1588, 159, t. xlv.; Prosper Alpinus, *De Pl. Egypti*, 1592, 38-9; Munting, *Phyt. Curiosa*, 1696-1702, 46, t. 239; Milburn, *Or. Comm.*, 1813, i., 292; Heyne, *Tracts on India*, 1814, 206; Taleef Shereef (Playfair, transl.), 1833, 59-60; Buchanan-Hamilton, *Stat. Acc. Dinaj.*, 1833, 174, 184; *Hobson-Jobson* (ed. CULTIVATION.—Sesame is grown as a pure crop all over India, and in certain localities, such as the United Provinces, also as a mixed crop. According to the *Agricultural Statistics*, the area in British India under the crop in 1904-5 was 4,023,847 acres. An estimated area for the same year, excluding Burma but including the Native States of Bombay and Sind, was stated at 4,178,700 acres for the pure crop with a yield of 300,400 tons; 600,000 acres for the mixed crop with a yield of 35,000 tons, the latter being in the United Provinces. In that year also the area in the Native States (as officially returned, but excluding Hyderabad, Kathiawar and Baroda) is stated to have been 487,277 acres. In Noël-Paton's *Final Memorandum* on the sesamum crop for 1905-6 mention is made of the area in Hyderabad having been 780,000 acres in 1904-5 and 431,200 acres in 1905-6. For the ten years ending 1905-6 the annual average area in British India, including Burma, was 3,904,000 acres, of which Burma had 930,000 acres; the Central Provinces, 832,000 acres; Madras, 737,000 acres; and Bombay with its Native States of Kathiawar and Baroda, 633,000 acres. For the years 1905-7 the estimated area and yield (excluding Burma) were:—1905-6, 3,914,200 acres (pure) yielding 344,800 tons, and 700,000 acres (mixed) yielding 45,000 tons; 1906-7, 3,844,100 acres (pure) yielding 441,100 tons, and 775,100 acres (mixed) yielding 90,000 tons.

There are two crops, a *rabi* and a *kharif*, and various cultivated forms of the plant, some specially suitable for growing in the *kharif* season,

TWO CROPS

A U
I ICU
Cultivation

others as early *rabi* crops. Two, at least, of these are easily recognised—one with white seeds (*safed til*), the other with black (*kala til*). The latter is much the more common form and is reputed to yield a superior oil.

The *rabi* crop is most extensively grown on black or medium black cotton soil in alternation with cotton or *juár*. If sown in September it is ready in January. The *kharif* crop is usually sown with other crops, such as *juár*, *bágra* and cotton, but is sown by itself in some localities. It ripens in October or November. A good average crop from black soil is said to yield about 450 lb. of seed per acre (*Imp. Gaz.*, 1905, iii., 38-9).

Bengal, including Eastern Bengal.—The estimated area and yield in 1904-5 were 493,700 acres and 59,000 tons. The actual area, however, was 414,200 acres. The largest areas (indicated by the returns for 1904-5) ordinarily are :—Maimensingh, 74,300 ; Pabna, 39,000 acres ; Angul, 34,500 acres ; Midnapur, 29,100 acres ; Hazaribagh, 27,700 acres ; Backerganj, 25,000 acres ; Jessore, 22,500 acres ; Noakhali, 13,600 acres ; Tippera, 13,200 acres ; Bogra, 13,000 acres, etc. The supplementary *Final Memorandum* for 1906-7 estimates the area for 1906-7 at 292,100 acres with a yield of 39,600 tons in Bengal, and at 221,800 acres with a yield of 25,400 tons in Eastern Bengal.

According to Roy, the best soil is an alluvial loam, high and well drained. The black variety is taken after *áus* paddy, the white after *áus* or *aman* paddy. In Dacca only white *til* is grown. The land is ploughed and harrowed in February and April and the seed then sown "6 seeds per acre." The crop is harvested in May-June, and the average yield is about "15 maunds per acre." In Orissa, the land is prepared and the seed sown for white *til* in June-July, and the crop harvested in November-December ; for black *til*, the seed is sown in September-October and the crop harvested from January to March. [*Cf.* Basu, *Agri. Lohardaga*, 1890, pt. 2, 35 ; Banerji, *Agri. Cuttack*, 1893, 89-90 ; Mukerji, *Handbook Ind. Agri.*, 1901, 274-5 ; Roy, *Crops of Bengal*, 1906, 82-3.]

Assa.—The area in Assam proper in 1904-5 was 8,376 acres and the chief localities Sylhet, Nowgong and Kámrúp. There are reported to be three different crops, viz. the crop sown in February-March in Sylhet, the August-October crop of the Brahmaputra valley, and the May-June crop of Manipur and Nowgong. According to F. C. Henniker (*Assam Crop Exper.*, 1900-1, app.) the average outturn in 1900-1 was found to be 283 lb. per acre. [*Cf.* Allen, *Assam Dist. Gaz.*, 1905, ii., 120-1.]

United Provinces.—As already indicated, sesamum is largely grown as a mixed crop in these provinces. The total area of the pure crop in 1904-5 was 304,097 acres, and the outturn (estimated) 13,900 tons ; of the mixed crop (estimated) 600,000 acres, and the outturn (estimated) 35,000 tons. The principal districts (according to the returns for 1904-5), where the crop is grown alone, are :—*Agra* : Hamírpur, 115,119 acres ; Jhánsi, 105,404 acres ; Banda, 35,164 acres ; Mirzapur, 17,663 acres, etc. The supplementary *Final Memorandum* on the crop for 1906-7 estimates the area under the pure crop at 309,200 acres with a yield of 36,200 tons, and under the mixed crop at 775,000 acres with a yield of 90,000 tons. It is a *kharif* crop, sown at the commencement of the monsoon and harvested in October and November. The method of cultivation is very rough. "The seed is sown broadcast after two or three hurried ploughings, and ploughed in. When grown with millet or cotton, it gains the benefit of the care which these crops receive. It is in this case either sown broadcast,

United Provinces

Seed. the seed being mixed with that of the principal crop before sowing, or it is disposed in parallel lines running across the field or along its margins. When mixed with other crops the amount of seed sown to the acre varies, of course, with the inclination of each individual cultivator. When grown alone, from 8 to 12 seers of seed are used."

Outturn. "Under the circumstances of its cultivation it is obviously impossible to frame any reliable estimate of its outturn per acre, which varies very greatly with the amount of seed sown. From 25 seers to 1½ maunds are commonly gathered when it is sown with *juár* or cotton. When grown alone from 4 to 6 maunds is the average return to the acre." [Cf. Duthie and Fuller, *Field and Garden Crops*, ii., 35-7 and t. xlii.]

C. Prov. **Central Provinces and Berar.**—The estimated areas in 1904-5 in the Central Provinces and Berar were 779,600 acres and 111,500 acres, while the estimated yields were 58,900 tons and 10,100 tons respectively. The actual areas were 858,664 acres in the Central Provinces and 111,718 acres in Berar. In the Central Provinces the chief districts were:—Sambalpur, 103,401 acres; Nimar, 98,785 acres; Rajpur, 98,680 acres; Hoshangabad, 78,487 acres; Jabbalpur, 68,992 acres; Chánda, 59,800 acres, etc.; in Berar:—Wun, 67,307 acres. The supplementary *Final Memorandum* for 1906-7 estimates the area at 783,900 acres and the yield at 69,600 tons.

Soils. Fuller (*Note on Outturn of Land under Crops in C. Prov.*, 1894, 22-4) says "it can be grown on almost the poorest land in cultivation, but is also a profitable crop on good soils, and is commonly sown on newly broken lands during the first two years of the reclamation. It requires a light monsoon rainfall and in this respect resembles cotton, the *til* and cotton harvests generally agreeing in character. Though classed as a monsoon crop, *til* is largely grown during the cold weather in the southern and eastern districts, good land in this case being devoted to it and a larger outturn gathered than is usually yielded by monsoon *til*." With regard to outturn, he states that "the present standards are 150 lb. per acre for the three northern districts, 250 lb. for Wardha and Nagpur, and 200 lb. for all others. They rather overstate the produce, save in the case of the Nerbudda and Nagpur districts, where they are decidedly too low." [Cf. *Rept. Land Rev. Settl. Nagpur*, 1899, 63; *Hoshangabad*, 1905, 28.]

Panjáb. **Panjáb and North-West Frontier.**—The estimated area and yield in the Panjáb for 1904-5 are given as 158,000 acres and 16,000 tons. The actual area subsequently returned for that year in the Panjáb was 113,200 acres, and in the North-West Frontier Province 4,901 acres were returned as under the crop. The largest areas in the Panjáb (in 1904-5) ordinarily occur in Gurdaspur, 30,479 acres; Multan, 13,295 acres; Kangra, 10,255 acres; Amritsar, 5,709 acres; Gurgaon, 5,242 acres; Hoshiarpur, 5,231 acres, etc. The supplementary *Final Memorandum* for 1906-7 estimates the area in the Panjáb at 94,400 acres with a yield of 8,600 tons.

Outturn. In the *Gazetteer* for Multan (1901-2, 217) it is stated that "the outturn is from 3 to 3½ maunds per acre, and the produce fetches the zamindar some 10 seers to the rupee, or Rs. 4 per maund. The crop gives fair returns and costs less to cultivate than most, as it can do with a light soil and moderate moisture, can be sown late, and requires very little looking after. The sowings take place in July, and the crop is cut in November." Seasons. Lawrence (*Valley of Kashmir*, 340) says it is a very common crop, sown

in April, and ripens shortly after rice. It is a delicate crop, injured by cold winds.

Bo bay and Sind.—Estimated areas, including the Native States, were given in 1904–5 as 793,900 acres in the Presidency and 83,700 acres in Sind, with yields of 52,700 tons and 5,300 tons respectively. The area actually surveyed in the British districts alone was 302,600 acres in Bombay and 79,772 in Sind. In Bombay (1904–5) the largest areas were Khandesh, 80,812 acres; Nasik, 54,989 acres; Panch Mahals, 46,768 acres; Ahmadabad, 33,524 acres; Kaira, 18,681 acres; Ahmadnagar, 16,731 acres; Dharwar, 16,446 acres, etc. In Sind—Upper Sind Frontier, 46,894 acres, etc. Although no returns are available for the year named, the crop is known to be very important in Kathiawar, Baroda and other Native States. The supplementary *Final Memorandum* for 1906–7 estimates the area and yield in Bombay (including its Native States) at 1,020,400 acres and 182,400 tons, and in Sind (with its Native States) at 62,100 acres and 4,700 tons. The method of cultivation is fully described by Mollison: “The *kharif* crop requires,” he says, “a totally different soil to that found most suitable for the *rabî* crop. *Til*, as a rain-crop, likes a sandy soil or light soil, whereas the crop which is sown in August–September, or later, grows best on black soil or on such soils as are retentive of moisture.”

Bombay.

Sind.

Crops.

Seasons.

The Kaira cultivation, he further says, is typical for the *kharif* crop. It is sown subordinate to *bājra* on sandy loam soils. Other subordinate crops are the usual pulses and fibre-plants. “The *til* seed rate is $\frac{1}{4}$ lb. or less per acre.” If sown as early as possible in the *kharif* season, harvest should commence in September–October. A good outturn as a subordinate crop he estimates at “80 to 120 lb. per acre.” As a *rabî* crop it is grown extensively alone on black or medium black soil. The rotation crops are cotton and *juār*. The field is repeatedly ploughed and harrowed during June, July and August. If sown in September, the crop is ready in January.

Rotation.

With regard to outturn, he estimates that a good crop in Khandesh yields from 320 to 360 lb. per acre, and the seed is worth 15 to 18 lb. per rupee. From a seed-rate of 1 lb. per acre, a crop experiment at Surat in 1895–6 gave an outturn of 372 lb. per acre, worth Rs. 25–13–3. The cost of cultivation is rated at Rs. 10–6–0 per acre. [Cf. Mollison, *Textbook Ind. Agri.*, iii., 90–4; *Crop Exper. Rept. Bombay Pres.*]

Yield.

Madras and Mysore.—The estimated area and outturn were 674,200 acres and 55,100 tons, but the actual area in Madras during 1904–5 was 755,475 acres. In Mysore the area was 90,623 acres. The chief districts of Madras in 1904–5 were Godavari, 83,939 acres; Vizagapatam, 83,337 acres; South Arcot, 68,218 acres; Tinnevely, 56,938 acres; North Arcot, 56,873 acres; Salem, 55,429 acres; Coimbatore, 47,334 acres, etc. The supplementary *Final Memorandum* for 1906–7 estimates the area and yield in Madras at 585,500 acres and 48,000 tons. In Godavari, it is stated that mixed or sandy soil suits the plant best. The land is prepared about the month of April and the seed sown in May or June. The crop is ripe about three months after sowing. In North Arcot it is said to be an early crop, being sown, if the rains are sufficient, in April or May, and reaped four months later. It is sometimes irrigated, and is then sown as early as January or February. [Cf. Cox, *Man. N. Arcot*, 1895, i., 271–2; Rice, *Mysore Gaz.*, 1897, i., 122; Francis, *South Arcot*, 1906, i., 114, 122.]

60,317 acres in Lower Burma. The largest areas were as follows:—Myingyan, 241,355 acres; Magwe, 185,386 acres; Lower Chindwin, 128,398 acres; Sagaing, 127,634 acres; Meiktila, 94,954 acres; Minbu, 77,176 acres, etc. The following facts regarding Myingyan (Carey, *Settl. Rept. Operat.*, 1901, 34), where the largest area is ordinarily grown, may prove instructive. "Early sesamum is sown in May and June and is reaped in July and August. Late sesamum is sown in October and November and is reaped in January and February. The early sesamum seeds are the *thadunbyu* (white), *boktaung* (red), *shan hnan* (large seed), and the late sesamum varieties are the *hnangi-net* (black) and *hnangyi-phu* (white). The same quantity of seed is sown for both crops. The late crop is the safer, but the early crop gives the larger yield. Invariably $2\frac{1}{2}$ *pyis* of seed are sown to the acre, and, whereas the early crops yield from two to twelve baskets (both extreme figures), the best late crops seldom exceed six baskets. A basket of seed gives 5 *viss* of oil, the value of which varies from Rs. 3 to Rs. 5 per *viss*, but Rs. 3-4-0 is the average normal sale value." [*Cf. Settl. Operat. Repts. for Parlett, Sagaing, etc.; Max and Bertha Ferrars, Burma*, 1900, 51, 149.]

MANUFACTURE AND USES OF THE OIL.—As indicated, there are at least two easily recognised forms, one with white, the other with black seeds. The latter is the most abundant and yields the best oil. It is extracted by expression in mills, by the same process as that for mustard-oil. Is clear and limpid, varying in colour from pale yellow to dark amber. Has no smell and not liable to become rancid. Adulteration with ground-nut oil is frequent. In India it is largely used for culinary purposes, in anointing the body, in soap manufacture, and as a lamp-oil. It is also frequently employed as an adulterant of *ghi* (see pp. 479, 481). In England it is chiefly used in making soap. In many of its properties it resembles olive-oil, and is accordingly similarly utilised. The oil from the black variety is generally stated to be more suitable for medicinal purposes than the white. It is also extensively employed in the manufacture of Indian perfumes, and for this purpose the perfume is frequently extracted by the seeds direct—layers of the seeds being placed between layers of flowers, etc. (see p. 820). The white-seeded form is largely eaten as an article of food, more especially in certain sweetmeats. The oil-cake, left after expression of the oil, is in demand all over India as a cattle food, and in times of drought and scarcity is even eaten as food by the poorer classes. As a manure the cake is of less value than castor and other oil-cakes. In Madras *tanghedi* bark (see p. 290) is said to be added to the seeds before being pressed for oil. [*Cf. Pharmacog. Ind.*, iii., 26-33; *Agri. Ledg.*, 1893, 1895-7, 1901, 1903-4; Basu, *Agri. Lohardaga*, 1890, pt. 1, 131; Banerjee, *Agri. Cuttack*, 1893, 197; Blount and Bloxam, *Chem. for Engin. and Manuf.*, 1900, ii., 233; Merck, *Digest.*, 1900, No. 7; Ludwig Hesse, *Physiolog. and Therap. Import. of Iodipin in Pharm.-Centralhalle*, 1900, No. 1; Thorpe, *Dict. Appl. Chem.*, 1900, iii., 377-8; Leach, *Food Insect. and Anal.*, 1905, 420; Leather, *Mem. Dept. Agri. Ind.*, 1907, i. (Chem. ser.), No. 2.]

TRADE.—Internal.—The returns of *til* seed carried by rail were in 1902-3, 4,590,935 cwt.; in 1903-4, 4,675,014 cwt.; in 1904-5, 3,627,307 cwt.; in 1905-6, 2,956,419 cwt.; and in 1906-7, 4,326,824 cwt. The chief importing centre is Bombay port, which in 1906-7 drained its supplies chiefly from the Central Provinces, Rajputana, Nizam's Territory and Bombay Presidency, viz. 2,738,978 cwt. Calcutta follows next with a total of 453,979 cwt., received from the Central Provinces and Bengal; then come the Madras ports with 384,156 cwt., derived from the Nizam's Territory and Madras. The traffic of Burma is not given in the returns of railborne trade, but it is doubtless mainly toward Rangoon and the other chief towns of the province.

The total exports by coast of sesamum seed in 1905-6 amounted to 479,169 cwt., valued at Rs. 37,69,577, and during the period 1900-5

averaged about 400,000 cwt. The chief exporting centres, coastwise, are Madras and Bombay, and the chief importing province is Burma. It is thus very significant that Burma, though it is the largest single producing area, drains an annual supply from India.

Foreign Exports.—In the foreign trade statistics the figures are returned under two headings—(1) Oil and (2) Seeds. The quantities of Sesamum OIL EXPORTED during the years 1902–7 were as follows:—In 1902–3, 212,728 gallons, valued at Rs. 3,33,489; in 1903–4, 285,711 gallons, valued at Rs. 4,24,403; in 1904–5, 547,456 gallons, valued at Rs. 7,22,158; in 1905–6, 308,310 gallons, valued at Rs. 4,44,293; and in 1906–7, 165,877 gallons, valued at Rs. 2,79,644. Almost the whole quantity goes from Bombay, and the chief markets in recent years have been Mauritius, Arabia, Aden, Ceylon.

During the period 1900–7 the exports of SEED were:—In 1900–1, 1,844,194 cwt., valued at Rs. 1,55,58,575; in 1901–2, 2,447,149 cwt., valued at Rs. 2,14,39,368; in 1902–3, 3,732,685 cwt., valued at Rs. 2,90,93,614; in 1903–4, 3,512,650 cwt., valued at Rs. 2,42,89,443; in 1904–5, 2,516,757 cwt., valued at Rs. 1,73,71,691; in 1905–6, 1,685,208 cwt., valued at Rs. 1,46,93,032; and in 1906–7, 2,740,815 cwt., valued at Rs. 2,53,79,919. It will thus be seen that a considerable fluctuation has taken place. Commenting on this subject, Noël-Paton (*Rev. Trade Ind.*, 1905–6, 43) observes: “The shortage in rape-seed led to an acute internal demand for sesamum and occasioned great embarrassment to shippers; and, since in this case also the favourable nature of the crop prospects had led to depletion of available stocks, the exports, which declined by 28 per cent. in 1904–5, underwent a further contraction of 33 per cent., making a total of 52 per cent. in the two years. The average value rose by 26·3 per cent.” The condition mentioned was, however, entirely changed by the recovery of the foreign transactions in the year following. Bombay exports almost the entire quantity consigned from India (in 1906–7 its share came to 2,366,144 cwt.), and the chief markets were:—France, 1,060,589 cwt.; Belgium, 862,117 cwt.; Germany, 311,553 cwt.; Austria-Hungary, 191,795 cwt.; Italy, 158,316 cwt.; Egypt, 110,515 cwt.; and by way of contrast it may be added that the United Kingdom took only 3 cwt., valued at Rs. 24. But, as already observed, while Burma is the largest single producing province, it exports practically no sesamum seed. The production must be locally consumed, and hence to Burma this is relatively a much more important product than it is to the people of India. In Burma this oil doubtless plays very largely the part of *ghi* in India.

The imports of sesamum oil and seed are small and unimportant, amounting, in 1906–7, to 384 gallons of oil and to 14,549 cwt. of seed, chiefly derived from the Straits Settlements and Ceylon, and consigned to Burma.

According to a recent volume of *Prices and Wages in India*, the wholesale price of sesamum seed in Calcutta in January of 1906 was Rs. 5–10–6 per maund of 82·286 lb.

ANIA ACUL ATA, *Pers.*; *Fl. Br. Ind.*, ii, 114; Prain, *D. P.*, *Beng. Plants*, 1903, i., 402–4; **LEGUMINOSÆ**. The *jayanti*, *brihat-chakramed*, *dhanicha*, *dhunchi*, *gadoreji*, *rán-shewrá*, *bhuavali*, *erra jiluga*, *nyaeh*, etc. A suffruticose annual met with often in a cultivated state on low-

lying land on the plains of India, from the Western Himalaya to Ceylon and Siam.

The stems of this plant have long been employed locally in various parts of India to yield a strong and useful fibre, which is used as a substitute for hemp. It is considered to be very durable under water, and is much esteemed by fishermen for making drag-ropes for nets. It is sown after the first showers of April or May, and the crop is ready to cut in September or October. The expense of cultivation is about Rs. 9 per acre. The method of preparing the fibre is similar to that for *san* (*Crotalaria juncea*). The stems are also commonly employed as stakes for *pán* (*Piper Bette*) gardens. Recent experiments at Sibpur and elsewhere have shown that it makes a good green manure. [Cf. Banerji, *Agri. Cuttack*, 1893, 88; Dodge, *Useful Fibre Plants of the World*, 1897, 294; *Exper. Farm Rept.*, Sibpur, 1897-8, 10; *Repts. Dept. Land Rec. and Agri.*, Bengal; *Admin. Rept. Bengal*, 1901-2, 20; *Dept. Agri. Mad. Bull.*, 1905, iii, No. 52.]

Early
Production.

Cultivation.—This millet is extensively grown in India both on the plains and the hills up to 6,000 feet, and is distributed to most warm temperate and tropical countries. It is interesting, for example, that the discoveries made at *Ancient Khotan*, by recent explorers, show that it was cultivated in Eastern Turkestan during at least the 3rd century of our era. Stein, for example, calls it *tarih*, and mentions specimens of the grain found at Niya and also at Kara-dong which had been identified at Kew. It is perhaps somewhat significant, however, that no reference should be made to it in *The Bower Manuscripts*, discovered at Kucha, seeing that two other millets are mentioned, viz. *Panicum Crus-Galli* (var. *frumentaceum*, see p. 843) and *Eleusine coracana*. The Italian Millet has often been claimed as an Indian wild plant, but the majority of writers now regard it as an exotic though cultivated from ancient times. It has, in fact, been grown from time immemorial in Asia, and has been recognised in the deposits of the Swiss Lake dwellings. De Candolle thinks that the species existed thousands of years ago in China, Japan, and the Indian Archipelago. The *kángni* of modern writers undoubtedly denotes this grass, and it is cultivated here and there all over India, and even in Burma and the Shan and Kachin hills. It delights, says Roxburgh, in an elevated light dry soil, and two crops may be sown on the same field, two separate sowings being made, and harvested in September and January. It is grown as a *kharif* crop mostly, and there are two well-marked varieties, one straw yellow, the other reddish yellow. Sen (speaking of Dacca) says it is very sensitive to stagnant water. If rain-water stands on the field for twenty-four hours the crop may be lost. Roy tells us that in Orissa it is generally grown by the hill tribes and confined to the jungle-lands. Mollison (*Textbook Ind. Agri.*, iii., 69) says that this millet is cultivated all over India, but in no part is the cultivation very important. "In Bombay Presidency the crop is annually becoming more popular and the area has considerably increased." "The total area for the Presidency exceeds 200,000 acres annually." It is a "quick-growing plant and a suitable crop to grow after a period of famine or scarcity." Mollison then adds that a Dharwar crop tested in 1894 yielded the following results:—Seed-rate 6½ lb.; grain 843 lb. and straw 2,631 lb. an acre.

Widely

Quick-growing.

Outturn

Diseases.—In Madras the crop is frequently attacked by a fungus, known as *Sclerospora graminicola*, some account of which is given by Barber in a paper on the diseases of *Sorghum* in Madras (*Dept. Agri. Mad. Bull.*, 1904, ii, No. 49), and by Butler (*Mem. Dept. Agri. Ind.*, 1907, ii, 14; also Maxwell-Lefroy, 1908, ii., 1-13).

ood.

Pastry.

Uses.—The grain is much esteemed as an article of human food in some parts of the country, and is eaten in the form of cakes or of porridge. In Madras it is specially valued as a flour to be used in making pastry, and when boiled with milk it constitutes a light and pleasant meal for invalids. It is also much valued as a food for cage-birds and for poultry, and added to beer it is said to make the

COWRY, CONCH AND CORAL

beverage more intoxicating (see p. 760). Church gives the nutrient ratio as 1: 7.4 and the nutrient value as 91. As FODDER, the straw is not reckoned very nourishing and is often only used as bedding or for thatching houses. [Cf. Sen, *Rept. Agri. Stat. Dacca*, 1889, 37; Banerjee, *Agri. Outlook*, 1893, 76-7; Roy, *Crops of Bengal*, 1906, 60; Lawrence, *Valley of Kashmir*, 1895, 337; *Mysore Gaz.*, 1897, i., 116-7.]

H LL.—Three groups of shells are of industrial value in India : D. P.
—(a) Cowries or shells used as money ; (b) Conch and other shells used for i., 429.
artistic and industrial purposes ; (c) Shells, freshwater and marine, utilised as sources of lime ; and (d) Ornamental Corals.

COWRY—*kauri*, *kavadi*, *kaparda*—the small white shell of *Cypræa moneta*. From time immemorial this has been employed in the currency of Southern Asia, more especially in China. The use is alluded to by Mas'udi (943 A.D.), by Marco Polo, and by many other writers, more especially of the Maldives, South India and Bengal. In India they are rapidly disappearing, though in the rural parts of the country they are still employed as money. Their value appears to be 6,144 to the rupee. But in addition they are largely employed as articles of adornment for horses, cattle, etc. The imports in 1901-2 came to 17,568 cwt., valued at Rs. 56,892; and five years later (1905-6) 21,405 cwt., valued at Rs. 81,710; and 1906-7, 18,638 cwt., valued at Rs. 68,845. The bulk of these foreign supplies came from East Africa and were imported into Bombay mainly, then Calcutta, Karachi, and last of all Madras. A considerable local supply is also obtained from the Laccadive and Maldivé Islands. [Cf. Watt, *Ind. Art at Delhi*, 1903, 206.]

Trade.

CONCH OR CHANK, MOTHER-OF-PEARL, ETC.—Thomas, *Pearl and Chank Fisheries*, 1884; Thurston, *Mad. Bull.*, 1894, No. 1. The sacred chank, conch or *sankha* (*Turbinella rapa*), is procured by divers in the Gulf of Manar, opposite Jaffnapatam in Ceylon, and off the coast of Travancore, Tuticorin, etc. Formerly the traffic in these shells was a State monopoly, to-day the Ceylon fisheries are regulated by an Ordinance. And so far as India is concerned, a notification is simply given when the sales will occur at Tuticorin. As much as a lakh and a half of rupees' worth is often disposed of at one time. But so long ago as the 16th century Garcia de Orta spoke of the trade with Bengal in these shells having declined, and Bocarro in the 17th century made special mention of the manufacture of bracelets from them. A right-handed chank (that is to say, one with the spiral opening to the right) is much prized by the Hindus to be used at their temples, and being exceedingly rare often fetches a high price. Bracelets, armlets, charms, etc., are made of the ordinary conch shell, and these have been used in India from time immemorial, such bracelets being known as *sankhas* and the workers as *sankharis*. It is somewhat curious that the chief centres of this trade are all remote from the localities of production—namely Dacca, Patna, Dinajpur, Rangpur, Bardwan, Balasore, Bankura, Sylhet, etc. Many of the smaller and more ornate shells are specially collected and used for personal adornment, or are worked up in fancy goods.

Li e.
Coral.

Ornamental.

Beads.

Imported Coral.

SHELLS, CORAL, ETC., used as sources of LIME (see p. 712).
CORAL—*murjân*, *mûnga*, *sangi-marjân*, *gûllî*, *pâvâlam*, *pagadan*, etc., is mainly of interest to India in the form of coral-reefs—modern or ancient—and hence sources of lime. Very little can be learned regarding indigenous ornamental corals. Mason, writing of the coast of Burma, mentions an elegant species of *Actinia* and of *Eandria* found in Amherst and Mergui. He also refers to a scarlet coral composed of cylindric tubes united together (*Tubipora musica*); a star-coral and tree-coral as plentiful on the coast of Tavoy. Black coral (*Antipatharia*) is also met with, of which beads are made and traded in from the Mergui Archipelago. Speaking of Tenasserim, Mason alludes to a tree-coral two feet long being of a deep scarlet often sold under the name of "Red Coral."

There are no properly constituted coral fisheries in India or Burma, and it cannot accordingly be said that we possess the information to decide whether or not any of the Indian species are of industrial value. The Indian trade in ornamental coral accordingly centres around the imported kinds, which, being foreign products, need not be dealt with in this work further than to mention the

extent of the traffic. In 1868-9 India imported coral to the value of £93,126. For the past five years the traffic has marked a decline in quantity but a rise in relative price. In 1902-3 India received 283,580 lb., valued at Rs. 5,47,258 (£36,484); and in 1906-7, 98,172 lb., valued at Rs. 3,27,773 (£21,852). The traffic is almost entirely from Italy and to Bengal.

HOR A RO U TA, *Gaertn. : Fl. Br. Ind.*, i., 306; *Ind. Stat. Atlas*, 1895, 29-30 and Map; *Gamble, Man. Ind. Timbs.*, 77-81; *Prair, Beng. Plants*, 1903, i., 254; *Duthie, Fl. Upper Gang. Plain*, 1903, 75-6; *Brandis, Ind. Trees*, 1906, 69; *DIPTEROCARPEÆ*. The *Sál* tree, *sál, sákhu, sarjum, sakwa, teturl, kándár, gúgal, kabbu, enkhien*, etc. A large gregarious tree, of which Gamble says: "The *sál* tree occupies two principal regions in India. The first is a belt at the foot of the Himalaya and running into its valleys and up its lower hills to 3,000 or 4,000 feet, and exceptionally, as for instance at Lansdowne, to a still higher altitude." "The second is the Central Indian belt, and the *sál* country begins on the Ganges near Rajmahal and passes through the Sonthal Parganas, Rewah, Chota Nagpur, the Central Provinces, Orissa and the Northern Circars, ending in the Palkonda range of Vizagapatam and the forest of Jeypur."

Resin.
Tapping.

When tapped, the tree exudes large quantities of an aromatic RESIN, whitish at first but becoming brown when dry. The method of tapping usually employed is in the month of July to cut out three to five narrow strips of the bark, according to the size of the tree, and about 3 or 4 feet from the ground. In about twelve days the grooves have filled up with resin. This is gathered and left to fill again. They give three yields, amounting in the best trees to as much as 10 lb. The first is the best in quality. A second yield in October and a third in January are also obtained from the same cuts, but small in quantity and inferior in quality. The resin usually occurs in small rough pieces, nearly opaque and very brittle, but Gamble states that in some parts of the Upper Tista forests, large blocks, 30 to 40 cubic inches in size, may be found in the ground at the foot of the trees. It is used chiefly to caulk boats and ships, also as an incense and in medicine. Hooper (*Rept. Labor. Ind. Mus.*, 1903-4, 25) says that it has a much lower acid value than pine resin, viz. 20 to 22, in place of 137 in imported pine resin and 124 in the Indian article.

Prospect.

The bark is said to yield a red and black DYE and to serve as a TAN. Recently an investigation into the value of *sál* bark as a tanning material was undertaken at the Imperial Institute, at the request of the Forest Department, and a report (*Imp. Inst.*, Oct. 7, 1904) was submitted by Dunstan to the Under-Secretary of State for India. Analyses proved that the bark derived from young trees was richer in tannin than that from old trees; moreover, that the young bark contained as much tannin as is present in oak, hemlock, and other barks commonly employed as tanning materials. Analyses of Indian-made extracts, however, showed these products to be of poor quality. Filtrates were better than solid extracts, both as regards solubility and tannin content, but "the best contained only 21 per cent. of tannin, whereas the ordinary tanning extracts in use in Europe contain at least 30 per cent." Experiments in tanning, both in the laboratory and on large-scale trials, were carried on by Dunstan at the Imperial Institute. In summing up his report, he observes that the results recorded show that it is quite possible to prepare from the bark of *Shorea robusta* an extract which, when employed as a tanning material, may furnish leather both of good texture and colour. It remains, he adds, to be seen whether the process devised by him can be successfully employed on a manufacturing scale in India. [*Cf. Hooper, Agr. Ledg.*, 1902, No. 1, 15-6.]

eed.
Famine Food.

The seeds ripen at the commencement of the rains and are collected and eaten Food, especially in times of scarcity. In *The Agricultural Ledger* (1904, No. 5) will be found a paper by Reinherz on the seeds of *Shorea* as a famine food. He gives a map showing the chief localities where the seeds are eaten, viz. in Chota Nagpur, the Sonthal Parganas, Gaya, Bhagalpur, Jalspaiguri and Orissa in Bengal; Gorakhpur in the United Provinces; Central India; and Chatrapur in Madras.

Ti ber.

The tree, however, is best known for its WOOD, which is the most extensively

employed of all timbers in Northern India. It does not, however, season well, but good specimens are said to be almost without a rival for strength, elasticity and durability. "It is in constant request for piles, beams, planking and railing of ridges; for beams, door and window posts of houses; for gun-carriages; the body of carts, and above all, for railway sleepers, the yearly consumption of which reaches some lakhs of cubic feet. It is used, or used to be used, in the hills of Northern Bengal, where it is found perhaps of the largest size now available, or making canoes. Owing to its not being floatable, difficulty is experienced in those *sál* forests which are in the hills, in getting the timber out of the forest on a log. The difficulty is, however, partially overcome by floating logs either with the assistance of boats or with floats of bamboos or light woods, such as *semul* (*Bombax malabaricum*)" (Gamble, l.c. 80). rh bifoli, Linn.; Cooke, *Fl. Pres. Bomb.*, i., 93; Duthie, *Fl. Upper Gang. Plain*, i., 81; Prain, *Beng. Plants*, 1903, i., 259. The *swet-verela*, *lal-berela*, *pitbala*, *bála*, *jangli-methi*, *athi-balla chettu*, *atibálá*, etc., and though more variable and perhaps less abundant, is also distributed throughout the tropical regions of India; MALVACEÆ.

The above, as also most other species, are very largely used by the Natives of India, being regarded as diaphoretic, diuretic, and demulcent, especially the root barks. The chief interest in them, however, centres in their beautiful bast fibres. Roxburgh, in 1832, wrote (*Fl. Ind.*, iii., 177) of the latter species that the bark yields "abundance of very delicate flaxy fibre, and I think might be advantageously employed for many purposes." Royle (*Fibrous Pl.*, 262), in 1855, republished that statement and added the opinion of Captain Thomson, who thought that from its "length, its similarity to silk, and its great strength, that it would fetch a high price in England. The line (only half an inch in circumference) sustained, after exposure to wet and sun for ten days, 400 lb."

Fibre.

Merits.

In the *Journal of the Agri.-Horticultural Society of India* (1881, vi., n.s., 224-8) particulars are given of a consignment of the "*burriala*" fibre submitted by the Raja of Bahihar in the district of Rajshahi. Upon that sample, Mr. Cogswell submitted a report, in which he complained of insufficient steeping and the presence of injurious "croppy ends." A later sample had been over-steeped and become "fozie." W. Stalkart asked if it could be produced as cheap or nearly as cheap jute? At the Colonial and Indian Exhibition, London, in 1886, a fair sample was shown by me to the fibre experts, who admired it greatly. The silvery colour was regarded as of importance in rendering it suitable for purposes to which jute could not be applied. Accordingly it was placed as superior to jute and the ultimate fibres were found to be much finer, thus rendering the fibre suitable for some of the purposes to which linen is put. In the *Journal of the Agri.-Horticultural Society of India*, 1890, viii., n.s., 124, Blechynden says: "A small plot of land was devoted to *Sida rhombifolia*, and the yield per acre found to work out to 5 maunds 19 seers cleaned fibre. It was stated that the plant did not grow well but was branchy, hence it was difficult to extract the fibre and the machine used could not deal with it properly." It was then

Recent Opinion.

valuation.

added (upon what authority is not shown) that "the retting process is not suitable for it." The ultimate fibres were found to be 1.5-2 mm. in length, and to be similar to jute in their reactions. It was, however, softer and more uniform. Chemically it showed a high percentage of cellulose (83.0 as compared with jute 75.0). [Cf. Cross, Bevan, King and Watt, *Indian Fibres*, 1887, 41-2; Watt, *Sel. Rec. Govt. Ind.*, 1888, 277-82.] The most recent opinion is that given by Mr. Robert S. Finlow (Pusa, July 25, 1907) in a report on experiments: "Sida is undoubtedly a fibre of very high class; it is far superior to jute; indeed it probably ranks nearer to flax and rhea. It is a common plant all over India, but it grows especially well in the moist climate of Assam. I have sown plots at Rajshahi this year, which are doing well" (*Rept. Agri. Dept. B. Beng. and Assam*, 1906-7, app. ii.). Samples were sent to the Imperial Institute, and valuations ranging from £12 to £18 a ton were obtained (*Imp. Inst. Tech. Repts.*, 1903, 59). The opinion given by Just Brothers of Bielefeld seems the rational one, namely that until a consignment of 400 lb. to 500 lb. of the fibre has been spun and woven, no definite conclusion can be arrived at.

ILK.—In perhaps no other country of the world does the necessity exist so pressingly as in India to treat the subject of silk and the silk industries under two distinct sections, viz. BOMBYCIDÆ, the Domesticated or Mulberry-feeding Silkworms; and SATURNIIDÆ, the Wild or Non-Mulberry-feeding worms.

I. THE MULBERRY OR DOMESTICATED SILKWORMS.

The terms mulberry and non-mulberry-feeding are more accurate than domesticated and wild, since certain of the so-called wild insects have existed for centuries, both in India and China, under what must be characterised as a degree of domestication; but, on the other hand, all the silkworms that live on the mulberry are not necessarily domesticated. "Wild silk" denotes, as a rule, the product of non-mulberry-feeding insects.

Habitat and Domestication.—The mulberry silkworm seems to be indigenous to the warm temperate regions of Northern China, and perhaps also of the adjacent countries. It was, for example, found by me in Manipur (during the Burma-Manipur Boundary Commission of 1882-3), under conditions that perhaps justify the suspicion that it may be indigenous, as well as long domesticated, in that little frontier State, if not of some parts of Bengal as well. But if it be not a native of certain warm temperate tracts of India proper, it occurs immediately beyond the Himalaya, more especially toward the eastern extremity, and at a very early period was successfully acclimatised on the extreme west in a tract of country just beyond the Kashmir frontier known as Khotan.

History.—In Buddhist Burma, where the objection to taking life prevails so strongly, a formidable barrier opposed any great extension of the industry, even although the Burmans for centuries past have been very partial to silk garments. Moreover, the silkworm exists on the hills of Burma and a distinctive race has for long been there reared—a fact that points to a considerable antiquity for the crafts of domestication of the worm, the reeling of the cocoons, and the weaving of silk. Moreover, a special tribe of people are identified with silk—the Yabein.

Turning now to China, it is customary to read of the silkworm having been reared from a vast antiquity (2,000 to 3,000 B.C., cf. Du Halde, *Hist. China*, 1736, i., 355-6), and of the secret of its value having been carefully guarded until well into the Christian era, when a princess, who married the Chief of Khotan, succeeded, at the risk of her life, in carrying off to the country of her adoption, seed of both the mulberry plant and the silkworm. This is reported to have taken place in 419 A.D., and in this way originated the silk industry and trade of Central Asia. A century and a half later, from Khotan a knowledge in silk was diffused to Persia on the one side and Greece and Rome on the other. The silk production of Central Asia became, in fact, the envy of Europe, and led to the formation of the silk-roads which were designed to facilitate the traffic in silk toward Rome. Procopius (*De Bello Gothico*, iv., 17, in Yates, *Text. Antiq.*, 1843, 231) tells the story of the monks of Serind (according to Yates—Khotan) having successfully carried the eggs of the silkworm to Constantinople (530 A.D.) at the invitation of the Emperor Justinian. This was desired so that the Romans might be able to produce the raw silk themselves instead of having to purchase it from their enemies, the Persia. A slightly different version of this story is told by Sir Thomas Herbert (*Travels, etc.*, 1677, 183-4), viz., "From the *Seres* or *Regio Serica* (part of Scythia towards Indus) this worm first came into Persia, not long before Alexander's time: but until the Emperor Justinian's time it was not known in Europe; the first being presented by the Persians unto the Emperor at Byzantium as a rarity." A curiously interesting confirmation of the tradition of the introduction of silk into Khotan has recently been brought to light by Stein (*Ancient Khotan*, 1907, 259-60) in the form of a painted wooden tablet found in the sand-buried ruins of Dandán-Uiliq, which Stein interprets as depicting the story of the Princess who carried off from China the silkworm eggs. There seems every reason for concurring that the tablet dates from the closing decades of the eighth century. One attendant is pointing to the headdress in which the eggs were secreted, and also to the basket of cocoons obtained therefrom, while a second is shown working at a silk-loom. The strongly Persian, in place of the Chinese, expressions of the faces is perhaps due to the stronger Iranian than Chinese influence at Khotan during that period, perhaps to some extent a direct consequence of the trade that had been by then established in silk. In Japan the domestication of the silkworm is perhaps very nearly as ancient as in China.

In India the mulberry worm has been systematically reared for many centuries, though it seems probable there have been two independent sources of the knowledge and stock possessed by India, viz. (a) Northern India, very possibly from Central Asia (Khotan) and Persia; and (b) Assam and Bengal, possibly from across the Chinese frontier, in all likelihood *viâ* the little State of Manipur. But it is curious and partly suggestive of the date of introduction to Northern India, at all events, that in the *Periplus* it should be stated that the silk came down the Indus (from beyond Bactria) and was conveyed to the great emporium Barygaza (the modern Broach), while no mention is made of locally produced silk. This is apparently, moreover, the first mention of the great

silk manufacturing industry of West India—an industry that subsequently drew upon Bengal for its supplies of raw silk. It would also seem highly probable that all the early references to silk by the Sanskrit authors denote one or other of the non-domesticated worms, not the true silkworm of modern commerce.

Races of Plant and Insect.

Briefly, then, it may be said that the domesticated silkworm has been carried to all the countries of the globe where it has been found possible to grow the mulberry plant. But just as there are several distinct species, and under these many very different races of mulberry, so there are numerous forms of the silkworm. Some of these are confined within narrow limits, both as to locality and food-plant, others are less restricted and have adapted themselves to a wider range of climatic conditions and food-plants. The Roman attempt at rearing the silkworm does not, however, seem to have made much progress, for the domesticated insect of modern commerce is commonly believed to have been conveyed to Europe somewhere about the 13th century, and has since been widely diffused. There were, however, repeated efforts at acclimatisation. For example, the worm was conveyed to Italy by King Roger II. of Sicily, who brought it from Greece along with Greek silkworm rearers, whom he compelled to settle in Palermo. So again, it was in 1440 carried from Naples to France. It is now met with in Italy (Lombardy), France (Central and South), Spain, Sweden, Russia, Turkey, Algeria, Egypt, Syria, Armenia, Central Asia, Persia, Afghanistan, Kashmir, India, America and Australia, in addition to Burma, Siam, China, Japan, Corea, etc. It everywhere thrives best and gives the finest silk where the climate is temperate and its food-plant one or other of the races of *Morus alba*. Under skilled treatment, both of the food-plant and of the insect itself, immense improvements have been effected in Europe, also in Japan, so that it is commonly said both China and India have fallen below the modern level of quality.

Second Introduction to Europe.

Italy.

France.

Temperate Climate.

Names.

As manifesting a common origin, the recurrence of the Tartar name *ser* and the Korean *sir* in many languages may be mentioned. Thus the Chinese *tsau* (cocoon), *tsi* (silkworm), and the Burmese *tsa*; also the *ser* in Greek; *sericum*, Latin; *seiden*, German; *soie*, French; *sheolk*, Russian; *seole*, Anglo-Saxon; *silke*, Icelandic; and *silk*, English. On the other hand, there seems little or no connection with these words and the names for the silkworm and silk in both ancient and modern India. The synonym *urna* (generally translated silk) occurs in the *Rig Veda*, but there is nothing to establish belief that it denoted mulberry silk. Another Sanskrit synonym, *patta*, gave origin doubtless to the modern Assamese and Bengali *pat* and the Tamil, *pattu*, for mulberry silk. In fact, *pat* occurs here and there throughout India and even in Kashmir, and uniformly denotes silk. So also the Sanskrit *pundarika* (silkworm) lives in the caste name of the silkworm rearers, the *pundari-kakshas* or *pundas*. The very common Indian name *resham* (silk) is derived from the Persian *abresham*, and is thus closely connected with the Hebrew *meshi* and *demeshek*, as also the Arabic *dimakso* and *kus*.

Life-history.

Life-history.—While the forms made specific by Hutton have by modern authors had to be reduced to races under the species *Bombyx mori*, the forms in question denote important industrial assemblages, which it is essential should be here briefly indicated.

It may be as well to sketch very briefly the life-history of the silkworm itself. Needless to say it exists first as an egg, then as a worm (or caterpillar), which later on spins a cocoon within which the chrysalis stage is spent, and lastly from the cocoon in due course emerges the winged moth, which, after coupling, lays eggs and dies, thus originating once during its lifetime the cycle above briefly indicated. The four stages (egg, caterpillar, chrysalis and moth) thus constitute one generation, and insects that take a year to pass through these stages are called *univoltine*. Occasionally special breeds are met with that are *bivoltine*, that is to say, a first batch of the eggs germinate almost immediately after being laid, thus allowing time for two generations in the year. The *bivoltine* insect of China was perhaps first introduced into Europe by the Genoese, but *trivoltine* insects occur in Tuscany, and even *quadrivoltine* forms are met with in many countries.

Generations.

In India a still more complex condition prevails, where the heat of Bengal and Assam causes the insects to become *multivoltine*. The *boropolo* (*barapalu*) insect (*Bombyx textor*) is univoltine, but the *desi* (*B. formatus*), the *madras* (*B. cræsi*), the *chotapat* (*B. sinensis*), and the *nyapaw* (*B. arracanensis*) all pass through a succession of generations in the course of the year, which sometimes amounts to as many as eight in number.

The crop of silk produced by a generation of worms is called a *band*. In Bengal the ordinary crops or *bands* are known as the November *band*, the March *band*, and the July *band*, but there is occasionally a fourth *band* attempted after the close of the July one, by such rearers as have sufficient calf.

Aristotle gives an interesting account of the silkworm, but he was not accurately acquainted with the four stages in its life. He does not say that it was reared in captivity but simply that Pamphile, daughter of Plates, was reported to have been the first to weave silk at Cos. Aristotle describes the spine or horn at the anal extremity of the worm, a fact that proves fairly conclusively, however, that it was the same species as the mulberry-feeding insect of to-day. But St. Basil (370 A.D.), a native of Asia Minor, gives full particulars of the stages and mutations of the silkworm, and he was the first to mention the popular suggestion of the parallelism of the escape of the moth from the chrysalis with the resurrection after death. Pausanias (in the 2nd century), also a native of Asia Minor, furnished particulars of the rearing-houses used in summer and those employed in winter by the silk-growers. Thus, when we first make acquaintance with the life-story of the silkworm, it had probably been by then as fully domesticated as is to-day.

The first scientific writer who can be traced is Andrew Libavius, who bred silkworms at Rothenburg and published his observations in 1599. He lays stress on the horn-like tail as the most distinctive character of the domesticated mulberry worm. But to the student of Indian sericulture a much more interesting publication appeared nearly a century later. In 1689 the Rev. J. Ovington wrote his *Voyage to Suratt*, in the Appendix to which there is given *Observations concerning the Nature of the Silkworms* (see pp. 1017, 1020). This was apparently aimed as an account of the silk of India generally and not of Surat alone, but it deals exclusively with the mulberry worm. It leaves the suspicion, therefore, that it may have had special reference to an attempted Surat industry of rearing silkworms, fully two centuries ago. He gives the utmost details as to the seasons of each *band*, then concludes—"This is the Nature of the Silk-worms in the Indies here the Heat of the Sun renders them much more fruitful than with us; for India the Worms breed and spin their Silk six times in the Year, and in England only once." "There likewise they are sooner brought to perfection, and begin to work sooner, viz., 28 days after they are hatcht, but in England not until the 40th. Here also they are by a third part more tedious in breaking out of their Houses on the first day of their Spinning than they are in the East, which is there done in ten days, but here only in fifteen." Herbert (*Travels, etc.*, 1677, 183-4) gives highly instructive account of the domestication of the silkworm in Persia. It is a univoltine insect fed on white mulberry, and he says, "In most Villages and Cottages we saw sheds filled with laborious People minding their enriching silkworms."

Races of Insects.—The following may be given as the chief races :—

(a)— *ori proper*, the European Silkworm.

It is customary by writers on the Indian silk production and trade to class all the races of the European worm as one, perhaps because under the Indian conditions the differences that exist become immaterial. Mukerji gives many interesting details regarding the directions under which the rearing of certain races of the European worm become possible in the plains. The eggs require to hibernate under considerably lower temperatures than those for the *barapalu* (slow)—viz. 30° to 40° F. But there are certain disadvantages, such as the fact that these worms usually die of *flacherie* if reared from April to August. They do not as a rule make good cocoons if fed on the ordinary shrub-mulberry of the region. They require to be fed on leaves gathered from trees. Where large mulberry trees are available it may be profitable to rear European cocoons. In

fact the opposite condition also prevails, namely the *chhotapalu* (presently to be described) do not make good cocoons if fed on leaves from tree mulberries. The reader desirous of full particulars of the methods to be pursued in rearing European silkworms in Bengal should consult Mukerji's work (l.c. 162-70).

Kash . . . In K hmir, largely through the great personal interest taken in the subject by Sir Walter Lawrence and Sir Thomas Wardle, much progress has been made in acclimatising the European silkworm (see p. 1016). [Cf. *Note on Sericult. in Kashmir, Baluchistan and Quetta*, in *Agri. Journ. Ind.*, 1907, ii., pt. iii., 286-7.] More recently similar efforts have been made in Assam (p. 1015), in Baluchistan (pp. 1016-7), and in Mysore (p. 1018).

Apparently the earliest notice of it occurs in a letter from Major Bogle and referred to by Fytche, Assistant Commissioner, Arakan (*Journ. Agri.-Hort. Soc. Ind.*, 1850, vii., 281-5). The best description of it, however, is that written by Mr. R. A. Manuel. It lives on the mulberry and the following are its stages—in the egg, 8 days; in the worm, 15-23 days; in the cocoon, 8-10 days; and in the state of moth, 2-3 days. Its cultivation in Burma, he further says, is careless, slovenly and dirty. No separate rearing-house is provided and the trays are never changed, the excreta never removed, nor the refuse food cleared out. It is no wonder, therefore, that the mortality is very high. The manipulation of the silk and the manufacture of the resulting fibre are alike indifferent, so that the industries connected with this special worm can hardly be regarded as more than of very local interest. The districts chiefly concerned are Tharawaddi, Promé, Thayetmyo and Toungoo. Breeding is confined to the higher tracts of the Pegu and Arakan Yomas. Still, the existence of a special breed of *B. mori* may either point to a great antiquity or denote the comparatively recent domestication of a peculiarly Burmese insect which with more careful inquiry may be found to exist even to-day in a wild or feral state, much as in the neighbouring State of Manipur.

Black Spots.

(γ)— *e. r. sl*, Hutton, *Trans. Entom. Soc.*, 1864, ii., 312; Cotes, *Ind. Mus. Notes*, i., pt. iii., 151; Quajet, l.c. 113. This is the *nistri* or *nistari* or *madrasi*, a multivoltine insect reared chiefly in the March and ra' bands of Bengal and Assam, where it is second in importance to the *desi* variety. It produces a succession of crops throughout the year, most of which are only reared for seed. But unlike the *desi*, however, it thrives best in the hot weather. Cotes (*Journ. Agri.-Hort. Soc. Ind.*, 1891, ix., 155) says the only real distinction between *desi* and *madrasi* is that while the former thrives best in the cold weather, the latter prefers the hot season. The cocoons are generally yellow, at least externally, and are somewhat larger than those of the *desi*, but the fibre has less elasticity and brilliancy. The moth is milky white in colour and the caterpillar has two black spots on each segment. Blechynden (*Journ. Agri.-Hort. Soc. Ind.*, ix., 156) suggests that the name *nistri* is due to these spots, the comparison being to the goddess Kali, an alternative name for whom is *Nistari*. Hutton says that it goes through all its changes from egg to cocoon in twenty-five days but in cold weather it takes thirty-five days.

Perhaps the earliest account is that given in the *Minutes of the Bengal Board of Trade in 1819* (cf. *Reports, etc., of Cotton, Silk, and Indigo* (pub. E.I.C.), 1836, app., 48-51). It is there stated that there are several distinct forms of the *nistri* worm, such as the "*madrassi*, *soonamooky*, and the *cramee*." As to the origin of these insects, it is stated that the "Bengals are not able to speak with the degree of precision it were to be wished." They are peculiar to Commercolly district, except the *madrasi*, which is also found in Bauleah, Soonamooky and Malda. The Resident at Commercolly was of opinion that the finest stock of *nistri* was that of Soonamooky. The *madrasi* are inferior but next to these. They all produce a silk of a greenish hue much inferior to that of the *desi*, but are much sought after as they yield a large amount of silk. It is a hardy insect, requiring little care and not at all choicely in its food.

The Resident at Malda wrote in the same papers that the *madrasi* silkworm is distinguished from the *desi* by a black mark under the throat. He then adds,

"Its great comparative defect is that it cannot be kept in store (in these *aurungs* at least) longer than a few days without total destruction, whereas the *desi* may be kept in well-aired cocooneries even twelve months without material injury." Speed (*Agri.-Hort. Soc. Ind. Trans.*, 1839, iii., 21) speaks of this as the *madras*i or *China pulu*, from which it may be assumed as possible that *B. sinensis* or *sina* (China) insect may be but a degenerate state of the *madras*i, the two names *sina* and *madras*i having in Bengal come to be accepted as synonymous. That may or may not be the case, but it cannot be too strongly urged that the early writers recognised several distinct forms of *nistri*, of which the *madras*i was one and by no means the best.

Several Forms.

Worm.
Indigenous.

As the name implies, this is viewed by the people of Bengal as an indigenous insect, though it is probable that it is in reality only so much anterior in its acclimatisation as to be viewed as relatively indigenous. Perhaps the first definite account of this insect occurs in the volume of official papers (E.I.C., l.c. 40-7). It is there stated to be produced throughout the year but to vary in estimation and value, according to the season of production and the nutritious nature of the mulberry-leaf upon which fed. "Hence, the worm of the cold-weather or November *band*, and that of the dry-weather or March and April *bands*, is superior from the more favourable state of the weather." Speed (*Agri.-Hort. Soc. Ind. Trans.*, iii., 20) speaks of this silkworm as of a small size but as yielding cocoons five times a year at periods of from 40 to 110 days. Hutton points out that the longer period occurs in the November *band*, hence its superiority. The official papers (E.I.C., l.c. 41) speak of the "Commercolly" *chassars* formerly raising no cocoons except the *desi* until the year 1790, when two sorts of *nistri* were introduced by Mr. B. Becher. It is, however, observed that the *desi* is the best of all the silkworms. The broods are October, November, March, April and June or July. The first is the best in point of quality, but the second the most productive. The Resident at "Cossimbuzar" (E.I.C., l.c. 42) describes the November *band* of *desi* silk as the largest in the year, but he adds that in his opinion the annual worm is as far superior to the *desi* as the latter is to the mixed breed of *desi* and China insect. He then remarks that in Cossimbuzar the April *band* is mostly the China insect. Similar reports are given from "Hurripaul, Jungypore, Malda, Radnagore, Soonamooky and Bauleah," thus showing the wide distribution of this insect at the beginning of the last century. Of Hurripaul, it was stated in 1819 that the *desi* had only just been introduced. In Soonamooky, on the other hand, the yield of silk from this insect in 1813 was 1,040 maunds of silk, and the Resident in Malda speaks of the produce from this particular insect having been in 1811, 2,708 maunds. He then adds that the cocoons produced in Bauleah and the vicinity in the November *band* alone, if a favourable one, are about 60,000 maunds.

Seasons.

Annual Worm
the Best.

Cleghorn recommended that in breeding the *desi* worm, it was imperative to select dusky moths. This observation regarding the dark-coloured insects and worms will be found to have a peculiar bearing on Hutton's opinion regarding the original form of *B. mori*, more especially when it is added that Mukerji, while experimenting with certain cocoons furnished by Cleghorn, arrived at the opinion that they "were a cross between the country breeds and *B. mori* of Europe." The domesticated and wild insects seen by me in Manipur would appear to belong to the *desi* race, a fact of no small importance in support of the belief that it is there indigenous (see below, p. 1015). Wild Insect.

(ε)—*. sinensis*, Hutton, *Trans. Entom. Soc.*, 1864, ii., 313; Cotes, *Ind. Mus. Notes*, 1889, i., pt. iii., 156. This is the *sina* (China) or *chota pāt* insect of the Indian sericulturists. It is a small multivoltine silkworm, which produces cocoons inferior to both the *desi* and the *madras*i. In Bengal its cultivation has been almost abandoned, though it would appear to be grown successfully on the hills and seems to be the chief multivoltine insect of the plains of Assam. Hutton, speaking of Mussourie, says it was in his hands very prolific and yielded crop after crop up to the middle of December. The cocoons vary in colour from being white, yellow or greenish coloured. Unlike the other Indian races, which hatch slowly during the morning (from 6 to 12 o'clock), the *sina* worms come forth all in a batch, hatching day and night till all are out of the eggs. In the volume of official papers (*Board of Trade, Bengal*, 1819) there are several papers that deal with

this insect; the reports are unfavourable, and speak of the breed having degenerated in Bengal. Of Cossimbuzar, for example, it was observed that there had been a great intermixing of *desi* cocoons with the China stock. The latter predominates in the April band, the distinctive mark being the length and thinness of the cocoon. This is considered by the rearers as the most inferior kind and "is nearly exploded as a distinct species."

(§) — *textor*, Hutton, *Trans. Entom. Soc.*, 1864, ii., 313; Wardle, *Wild Silks in India*, 1881, 2; Louis, *A Few Words on Sericult. in Bengal*, 1880, 20; Rondot, *L'Art de la Soie*, 1885, i., 320; Quajat, *Dei Bozzoli*, 1904, iii.; Cotes, *Ind. Mus. Notes*, 1889-91, i., 154; Mukerji, *Handbook of Sericult.*, 1899, 155-62. The *boro polo* or *barapalu*—Large Pát—the annual silkworm of Bengal. Speed (*Agri.-Hort. Soc. Ind. Trans.*, 1839, iii., 19-20) fixed the date of the introduction of this insect into India, viz. 120 years before the date of his paper, etc. He further says that it came from Italy. There is no confirmation of these views in any of the records I have been able to consult.

Cotes speaks of this as an annual mulberry silkworm, larger than either the *desi* or the *madrasí*. In the official papers issued 1819, it is stated that in the district of Cossimbuzar this insect predominated in the March band; moreover it was added that in the Cossimbuzar factory that band was second in quantity but first in quality of all the bands in the year. Of Bauleah it was remarked in 1817 that not a cocoon of this description was produced. On the other hand, the Resident at Hurrupaul spoke of it as the most valuable and as yielding the best silk in the March band. Of Jungypore, it was stated that notwithstanding every exertion, the production of this cocoon had become exceedingly precarious and uncertain. Radnagore reported that in a good season this insect was very abundant and profitable and produced in the proportion of at least two to one of the other species. The Resident of Soonamooky observed that the eggs are brought out for hatching about the end of January and in 40 to 45 days the cocoons are complete. This insect, he added, is, however, most difficult to rear and is much more delicate than the others. But the silk is of fine fibre and strong, and ought to be very mellow to the feel and of clear yellow colour with some white. The yield is about 103,500 *khauns*, which ought to yield about one hundred and fifty factory maunds of silk.

It is at present occasionally reared in Assam and Bengal, but owing to the fact that it produces but one crop of cocoons in the year and that its eggs do not hatch simultaneously, its cultivation has now been almost abandoned. To-day Mukerji deprecates the decline in production that has taken place. "The *Barapalu* is reared," he says, "by very few people. There are two reasons for neglecting such a superior class of cocoons:—(1) The eggs of the *Chhotapalu*, the *Nistri-palu*, or the *Cheenapalu* take only eight to ten days to hatch, but the eggs of the *Barapalu* hatch after ten months; (2) *Barapalus* go on hatching for seven or eight days or still longer, while the eggs of the other varieties of Bengal silkworms hatch completely in two or three days, when once the hatching does commence." Mukerji makes the practical suggestion that if arrangements could be made for hatching *barapalu* eggs in certain central establishments and distributing hatched worms to villages instead of eggs, the rearing of *barapalu* could be made to assume some importance. Mukerji (*l.c.* 159) gives many useful particulars regarding the methods of storing and hatching the eggs, and shows that by subjecting them to a fairly low temperature for a fortnight, followed by a similar period of warm temperature, the eggs may be caused to hatch at any time desired, thus producing pseudo-broods as leaf may be obtainable. Naturally, they hatch in January and the cocoons are obtained in February, and from them four pseudo-broods may be taken, viz. a second brood in March, a third in September, and a fourth in October. Rondot writes that this variety spins a white cocoon smaller than that of *B. mori* and differing from it both in form and structure, being generally pointed at both ends, a little soft, the silk not closely wound and containing comparatively little gum.

MULBERRY-PLANT CULTIVATION.—(see orus, pp. 784-5). In the temperate tracts of India various forms of *Morus alba*, Linn. (the mulberry of the European silk-producing countries), are grown specially as food for the silkworm. This is the case in many parts of the plains of Northern India, Baluchistan, Afghanistan, Kashmir, and along the Himalaya at altitudes up to 11,000 feet. The other species even more largely grown

for the Indian silkworm is *M. indica*, Linn., of which there are many distinctive varieties or races. This is the most common mulberry of Bengal and Assam, as also of the Nilgiri hills. The plants are usually raised under what is called the bush system, the standard or tree system being hardly if ever seen in these localities. It is, in fact, only in Bengal that shrub mulberries are produced systematically and at a cost of Rs. 20 to 25 per *bigha* (one-third acre). There is but one advantage of this system, namely that the leaf produced is preferred by the *chhotapalu* insect. Mukerji strongly recommends that mulberry trees should also be grown within or around the plantation, and for that purpose he suggests *M. alba*, var. *atropurpurea*. It is a fast-growing plant; the leaves are large and thick and at the same time smooth, tender and succulent. *M. serrata*, Roxb. (the *karin* or *kimu*), *M. laevigata*, Wall. (the *kimbu* and *taupwesa*), though wild, the former on the western and the latter on the eastern Himalaya and the mountains of Assam and Burma, are not to any material extent employed as food for the true silkworm.

Buchanan-Hamilton (*Stat. Acc. Dinaj.*, 210-3) gives particulars of the method of cultivation of the mulberry and the feeding of the worm that prevailed in Bengal during the closing decade of the 18th century. In the volume of official papers on the cultivation of mulberry, issued by the Bengal Board of Trade from 1813 down to 1836 (*l.c.* 63-113, 130-163) will be found a special report by Roxburgh entitled *Observations on the Indian Mulberry Tree*, *M. indica*, Linn. (*l.c.* 69-71), and also a similar paper by Wallich (*l.c.* 130-3, in which he describes *M. indica*, *M. atropurpurea*, *M. leptostachya* and *M. serrata*). These reports give a full record of the early experiments at improving the Indian silk by the production of better food for the worms, and are exceedingly instructive and valuable. Mukerji (*Handbook of Sericult.*, 1899, 1-4; also *Monog.*, *l.c.* 5-9) deals with present methods and opinions. "All varieties of mulberry are not equally suited," he says, "for rearing every kind of silkworm. The mulberry tree which we usually see in gardens, which yields large-sized black-coloured and luscious fruits is *M. nigra*. The leaves of that tree are rather coarse and not quite suitable for rearing silkworms." He then says that if the *chhotapalu* worm be reared on *M. nigra* it readily takes the disease *flacherie*, and the other forms of the insect, if reared on the black mulberry, yield a less proportion of silk and that of an inferior quality. Mukerji then adds that *M. multicaulis* may be regarded as the best for rearing silkworms. He doubtless means the Chinese and Philippine plant described by Perrotet, and which Rafinesque discusses in detail. [*Cf. American Manual of Mulberry Trees*, 1839, 64-6; also *Fl. N. America*, 1836, pt. iii., 48.] The attention of the Madras Government was drawn to this species of mulberry by Col. Sykes in 1839, and a supply was procured by Wight and grown in the Horticultural Society's gardens, Madras, about 1840, and a little later was taken to Bangalore and the Nilgiri hills. The leaves are large and tender. They are thick but not coarse. The tree grows fast and attains a greater height than other varieties. The internodes are short and the yield of leaf accordingly high. It is doubtless one of the many varieties or races of *M. alba*. As a curiosity it may be added that the American Osage orange (*Maclura aurantiaca*, Nutt.) has been introduced into India and found useful for rearing mulberry silkworms of all kinds.

Mulberry Plant

But in the early stages of the life of the worm it may be fed on the tender young leaves of the *pīpal* (*Ficus religiosa*). This fact is of considerable practical value when in spring the mulberry of Bengal is in a backward state.

Diseases of Mulberry.

Diseases of the Mulberry.—Mukerji (*l.c.* 121-7) discusses the diseases to which the mulberry trees are liable. The most serious appears to be *tukra*. This is caused by a minute scale-insect (*Dactylopius bromelie*). When attacked by this disease the leaves become curled up and the tender shoots swollen. When eaten they are shortly after voided by the silkworms, and if consumed to any material extent cause *flacherie* or *grasserie*. *Tukra* accordingly does much harm to the silk industry from January to June, and the only cure is the application of kerosene emulsion. Another somewhat similar disease is known as *naicha*. This is also caused by a member of the Coccidæ. It would seem the case that bush mulberries are much more liable to these diseases than tree mulberries. Mukerji observes that all the silk districts are not equally affected by *tukra*. In Murshidabad it prevails to such an extent that if it had not existed, there could have been obtained at least a third more leaf and therefore a third more cocoons. In Malda, Birbhum and Bogra very little damage is done by *tukra*—due possibly to greater intelligence in cultivation. Tree mulberries once started require little attention and are much less affected by dry, hot weather or disease.

Tukra.

Vaicha.

Consequences.

Fungal Disease.

Butler (*Agri. Journ. Ind.*, ii., pt. i., 97-8) gives useful particulars regarding a fungal disease seen on the mulberries of Kashmir. The State plantations near Srinagar had been seriously attacked. The disease is found on old trees without causing appreciable damage, but does great harm to the young plants in the nurseries. It attacks the seedlings in their second and subsequent years, does not kill them outright, but they have to be cut back below the diseased parts, thus losing several years' growth, even if they are not attacked again. The disease is caused by a parasitic fungus (*Coryneum mori*) which invades the wood or the branches, and comes to the surface to form spores. Butler adds, after his detailed description of the fungus, that it has previously only been found in Japan, where it was first described in 1904. It is thus probable that it was introduced into India during one of the attempts made to apply Japanese methods in Indian sericulture.

Introduced from Japan.

Rent of Land.

Rent of Mulberry Lands.—Some share in the decline of the Bengal silk industry has been attributed to the high and differential rents charged for mulberry land. Insufficiency of nourishment, due to dearness of mulberry-leaf, was, it has been said, one of the chief causes of the low yield and low quality of the silk. But Mr. Finucane (in an official paper) argues that the land usually placed under mulberry is valued for growing sugar-cane, tobacco, potatoes, and that accordingly if mulberry cannot hold its own in popular favour against these and such like crops, it would be unwise and pernicious to "prop it up by factitious encouragements." He then continues, "There can be no doubt that the rates of rent for high land on which mulberry is grown are higher than for low rice land, which is of a different quality; but the real question is—are the rates charged when mulberry is grown, higher than the rates which would be charged for the same land if sown with sugar-cane or potatoes or other upland crops?" He then answers that question by showing that in some districts an illegal practice does prevail of charging special rates for mulberry

Alternative Crops.

Special Rents.

cultivation. But the position of affairs is summed up by the opinion that such special rents are not general, and that they have "not really had much effect in bringing about the depression in the silk industry in Bengal."

Diseases and Enemies of the Mulberry Silkworm.—From 1865 to 1870 Pasteur devoted himself to the study of the diseases of the silkworm, and the remedial measures which he recommended have since been not only widely adopted in Europe but throughout the silk-rearing regions of the world. Even in India, thanks to the energy of the late Mr. N. G. Mukerji and his coadjutors, the selection of seed by the aid of the microscope has become an every-day practice of the ordinary cultivator, who may be said fully to recognise the value of specially selected seed in the curtailment of disease. A voluminous official correspondence exists in the *Annual Reports of the Dept. Land Rec. and Agri.* and in the *Proceedings of the Govt. of Bengal* on the subject of the diseases of the silkworm, especially the papers for 1894 and 1895.

Selection of
Seed.

The chief diseases are :—

(a) **Pebrine.**—This is known in Bengal as *kata*, or, in an aggravated form, *ali*, and characterised by the presence of microscopic corpuscles of an oval shape found within the tissues of the worm, but also in the moth and egg. Though not always fatal, this disease damages the quality of the silk very greatly. Besides being contagious, it is also hereditary. The cure is to breed only from eggs laid by healthy females (established by a microscopic examination) and general sanitary precautions to prevent infection. This is the worst of all the diseases, and, according to Mukerji, it was unknown in India twenty-five years ago (*l.c.* 2, 53-4). The final conclusions and recommendations deserve to be most carefully considered and enforced. [*Cf.* Fisher, *Ind. For.*, xv., 165-7; Arbousset, *On Silk and Silkworm* (Engl. transl.), 1905, 203-5.]

Pebrine.

Worst Disease.

(b) **Flacherie or Gattine.**—This is known in Bengal as *kala shira* or *shalfa*, and is characterised by the presence of "chain ferment within the digestive tract of the worm and pupa." The disease is contagious, and to a certain extent hereditary, in that the larvæ of moths that show symptoms of *flacherie* have a predisposition to the disease. The remedy is as above, namely, for breeding purposes to reject all eggs obtained from moths found by microscopic examination to manifest signs of the chain ferment. [*Cf.* Mukerji, *l.c.* 95-109; Fisher, *c.* 167-9; Arbousset, *l.c.* 206-11.]

Flacherie.

Microscopic
Selection.

(c) **Musccardine.**—This is known in Bengal as *chuna* (or *chunâ-kété*)—a name that indicates the resemblance to lime—and is caused by a fungus, which appears as a white efflorescence on the body of the worm some hours after it has died of the disease. It is contagious but not hereditary, and though the affection may be so slight as not to interfere with the spinning of the cocoon, the chrysalis almost invariably dies, and thus never emerges as a moth. The disease is spread by the spores produced on the efflorescence, so that the speedy removal of all dead worms is an efficient preventive to a dangerous outbreak. Next to *pebrine* this does the most harm in Bengal. [*Cf.* Mukerji, *l.c.* 74-87; Fisher, *l.c.* 167; Arbousset, *l.c.* 195-202.]

Musccardine.

Removal
of Dead.

(d) **Grasserie.**—This is the disease known in Bengal as *rasa*. It is of little importance, and is never hereditary. Following *musccardine*, it does, however, considerable damage to the worms in Bengal. In Europe it is not looked upon as serious, but in Bengal it becomes often epidemic. It invariably follows a heavy downpour of rain, if that succeeds to a long period of drought and high temperature, especially if the worms be then in their last stage of growth. Worms reared on mature leaf first, and tender leaf afterwards, are liable to take *grasserie*. The means of checking the disease is the propagation of large mulberry-trees. Whenever there is a sudden shower of rain, leaves from trees, not shrubs, should be given. [*Cf.* Mukerji, *l.c.* 87-95; Fisher, *l.c.* 169-70; Arbousset, *l.c.* 192-4.]

Grasserie.

Follows Rain.

(e) The most serious pest is the Tachinid fly, *Trypoxyna bombycis* (*Ind. Mus. Notes*, i., 83-8). This parasite lays its eggs upon the body of the worm. These eggs on hatching produce a grub that lives within the body of the worm and finally kills it. [*Cf.* Mukerji, *l.c.* 112-21.]

Parasite.

Influences of Climate.—It may be briefly said that in no essential feature are the mulberry worms of India different (as far as liability to disease is concerned)

from those of Europe, America or the Colonies. Perhaps the chief difference lies in the climate enfeebling the insect by causing it to produce too many broods in the year. But the prevalence of certain of the above-mentioned diseases uncontrolled is doubtless the chief cause of the decline of the Bengal industry. Mukerji (*l.c.* 41-53), in an introductory chapter, discusses the general aspects of the diseases of the Bengal worm, and makes many highly practical recommendations. About 60 per cent. of the silkworms, he says, die immediately after spinning a cocoon and after having eaten the full quantity of leaf. On this account the silk-rearers have for the past twenty-five years or so (in other words, subsequent to the appearance of *pebrine*) been steadily giving up their ancestral craft and taking to ordinary agricultural pursuits. There would seem no great reason why this wave of unpopularity could not be stemmed by vigorous efforts to assist and educate the rearers in the methods essential to the control of the plague.

Supposed Effect
of *Pebrine*.

Rearing-houses.

Grainage, or
Selecting-
house.

Hereditary
Rearers.

Mukerji gives many interesting details (*l.c.* 128-50) regarding the construction of rearing-houses, where the selection and improvement of stock might be conducted, and the elimination of disease by the microscopic selection of eggs. The grainage, he urges, should be established close to a large tank or river; should be surrounded by mulberry trees; should be one mile away from cocoon-rearing villages, filatures or cocoon godowns; and should be in a village where a sufficient community exists conversant with the picking of ripe worms, handling moths and planting mulberries. It is not possible to conduct sericulture under hired labour, if the workers are not drawn from the hereditary silkworm rearers. This point is of vital importance, as it takes many years' careful training to acquire the expert knowledge essential to success.

Wild ilks.

II. THE WILD SILKWORMS—THE SATURNIIDÆ.

Out of the long lists of wild insects that have been published by writers on this subject, only three Indian and two Chinese and Japanese species are of commercial importance. These are:—Indian-*Tasar* silkworm, *Antheraea paphia*; the *Muga*, *A. assama*; and the *Eri*, *Attacus ricini*: Chinese-*Tasar*, *Antheraea pernyi*: and Japanese-*Muga*, *Antheraea yamamai*. The last two insects are only mentioned here because they come into trade in opposition to the corresponding Indian insects, and on that account have been classed by the trade as forms of *tasar* and *muga* silks.

Names.

Tasar silkworm of India, a name which in English commerce is often written "*tussur*" or "*tusser*," and in French "*tussore*." It is usually said to mean a shuttle, and to be derived from *tasara* or *trasara* in Sanskrit, but neither of these words are employed by the older authors to designate a particular form of silk. Mr. A. Yusuf Ali points out that the letter "t" in the word for shuttle is the soft dental, while in the word *tasar* silk it is the sharp palatal "t"—two letters that are not often inter-

changeable. The English rendering *tussur* (if pronounced *toosoor*) would be quite unintelligible to the Natives of India. Equally absurd are the renderings *tussah*, *tusseh* and *tusha*. [Cf. Milburn, *Or. Comm.*, ii., 158, 244.]

Rumphius gives an interesting account of this insect, and appears to be the first European to call it *tasar* (or, as he wrote it, *tesser*), and the word must even then (1691) have been well known, seeing that he was able to contrast the insect of the Moluccas with that of Bengal. James Petiver (who died in 1718) gives a picture of the cocoon, and speaks of obtaining specimens from Madras through Edward Bulkley and Sam Browne. [Cf. *Phil. Trans.*, 1701, No. 271, 843; Yule, *Diary of William Hedges*, ii., app. cccxx.] But an even earlier usage of the word denotes a fabric of striped silk and cotton, the silk being either *tasar* or *muga*. Thus, for example, in the *Ain-i-Akbari* (1590) we read of *tasar* selling at Rs. $\frac{1}{2}$ to Rs. 2 a piece.

Other vernacular names are used to denote this insect, or, rather, special forms of it. We read of the *tasar* found in Bengal on the *ber*-tree (*Zizyphus*) being called *bughy*; that found on the *asan*-tree (*Terminalia*) being the *jarvo*; in Manbhum, the *tasar* insect is known as *daza*, *daba*, and in Santali it is *lumam*, *lumang*; in Bhagalpur and Dinajpur (according to Buchanan-Hamilton) it is *jaru*; in the United Provinces it is *koa* (cocoon), and the insect that lives on the *ber* is called *kuswari*, and that on the *asan* the *tasar*; and in Assam it is often distinguished as the *katkura*, while in the Deccan the name *kolissura* is sometimes given to it. Roxburgh calls the insect *bughy*, and the silk spun from its cocoons *tusseh*.

Habitat and Races.—According to Sir George Hampson it is a native of China, India and Ceylon. It may be spoken of as a denizen of the upland forests inhabited by the Santhal, the Kol, the Khond and the Gond, extending west and south-west of the Gangetic alluvial basin. In other words, commencing at the Rajmahal hills, it stretches through Karackpore, Chota Nagpur, Orissa, the Central Provinces, the Northern Circars to Hyderabad. It has thus the Ganges for its northern boundary, the Godavari for its southern, the coast ranges of Orissa to Ramgar in Hyderabad for its south-eastern, and the Nerbudda river and the Kaimor mountains for its north-western boundary. But it crosses these limitations at various points, as, for example, it passes the Ganges and enters Nepal, Sikkim, Assam, Manipur and Chittagong. It has also been recorded in Mysore. Beyond the special tract indicated, it is everywhere else more a curiosity than a commercial product.

There are several varieties or races of this insect (*Fa. Br. Ind.*, l.c. 19):—"The form *mylitta* is the most yellow; *paphia* is pale brownish-yellow; *nebulosa* greenish-brown, clouded with fuscous as far as the postmedial line; while *cingalesa*, from Ceylon, is a dark brownish-yellow form."

Se i-do estication.—The term domestication can hardly be applied to the method of rearing this insect pursued in India, and still in many localities it is not strictly speaking wild. The chief districts of production are Bhagalpur, Chota Nagpur and Orissa in Bengal, and Chattisgarh, Nagpur, Nerbudda and Jabbalpur in the Central Provinces. But the experiments performed some years ago at Poona proved that, so far at least as Western India was concerned, the expectations often advanced

of greater success from special cultivation over restricted areas, as compared with collection by the ordinary method from wild sources, were misleading. The semi-domestication that ordinarily prevails is to endeavour to grow (or rather to encourage the natural growth), within a certain tract of country, the tree or trees on which it is intended to rear the insect. The seed cocoons are collected from the jungles and tied on to the trees. Thereafter men and boys, armed with pellet-bows, guard the insects, as far as may be possible, against their enemies—chiefly flocks of birds that would greedily devour the caterpillars. In some few localities specially selected cocoons are reserved from last year's supply for the purpose of seed, and it is even occasionally the practice to allow the moths to make their escape from the cocoons under confinement, and to retain the females as prisoners in a position where they may be visited by the wild males, and thereafter to tie the little cages or baskets containing the eggs on to the trees. But it has been proved beyond dispute that the worms will not feed properly in captivity. The pairing of the moths and the production of the eggs may be accomplished under cover but the feeding must be done in the open air. Moreover, the worms are very timid, and must not be disturbed while feeding. In some localities they are carried from one tree to another when the supply of leaf runs short, but even this degree of interference is resented, and the worms seem never to form proper cocoons when any such interruption has occurred during the vigorous feeding stage.

For more than a century continuous efforts have been made in India to improve and extend the traffic. In 1796 Michael Atkinson (a correspondent of Roxburgh's) wrote: "This species cannot be domesticated. I am informed that the Natives cannot even retain any of it for seed. The hill people say that they go into the jungles, and under the *byer* and *asseen* trees they find the excrement of the insects; on which they examine the trees, and on discovering the small worms, they cut off branches sufficient for their purpose, with the young brood on them; these they carry off to a convenient situation near their houses and distribute the branches on the *asseen* tree in proportion to the size thereof, but they put none on the *byer*." The Board of Trade of Bengal published in 1819 a series of reports on the "*tussah*" silk, one of which is entitled *Modes of rearing the Gutis* (*gootee* = cocoon). "The seed is purchased from the jungle people, who collect it in August. Plots in the forest are appropriated for rearing where the *ashan*, *sal* and *sejah* trees predominate, particularly the first, which constitutes the best food. These spots are carefully cleared of other trees and shrubs annually. Just before the perforation, the seed cocoons are tied on to the trees. The rearers live in huts erected on the plot, keeping guard night and day with pellet-bows to drive away kites, crows and other birds."

These two passages may perhaps suffice to show that a century ago the system pursued was in every detail that followed to-day. But, as already mentioned, some thirty years ago Major Coussmaker conducted, on behalf of the Government of Bombay (*Admin. Rept. Bomb.*, 1876-7, 172; Coussmaker, *Rept.*, March 14, 1883), extensive experiments in order to ascertain how far the Native system might be simplified and improved. He made many important discoveries and solved most of the obscure problems of the life-history of the insect, but at the same time his results demonstrated conclusively that in Poona at least, the insect could not, under any degree of domestication, be reared profitably. Accordingly his final report expressed the opinion that systematic *tasar* silk-growing would not pay. Another practical investigator, Mr. W. Coldstream, though he formed a slightly more favourable opinion than Major Coussmaker, admitted that the future of the industry would depend on whether it could be made to pay. Coldstream, moreover, worked with a view to discover if *tasar* silk production could be engrafted on the village industries of the Panjáb, rather than the establishment of a large commercial industry. Mr. H. C. Cookson wrote a monograph on *The Silk Industry of the Panjáb* (1887), which republishes, as an appendix, Coldstream's report of his experiments. Later on a second monograph on *The*

Silk Industry of the Panjab was written by W. M. Hailey (1899), which once more reviewed Mr. Coldstream's experiments.

The insect lives essentially in the forests remote from the railways and centres of commerce, and in tracts of country unsuited to European life. Even to the Natives, the occupation of *tasar* silk rearing can hardly be viewed as a favourite one, for in addition to having to leave their homes and to take up temporary residence in the jungles, they have to submit to austerities enjoined by religion that make the occupation a punishment rather than an enjoyment. Moreover, the advances of agricultural occupation are daily pressing the area of possible *tasar* silk production farther and farther away, hence it can easily be understood why the cocoons, even when collected from purely wild sources, can hardly be conveyed to the nearest railway station at a price at all likely to command a ready sale. Mukerji suggests that the most practicable way of introducing the *tasar*-rearing industry in a new locality is to settle a number of Sonthal families, acquainted with this industry, in the new locality. The Sonthals have a hereditary affection for the *tasar* caterpillar and certain notions regarding its treatment, acquired from childhood. This affection and these notions enable them to watch patiently the worms all day and at all seasons. They have also the conviction that they are personally liable to supernatural visitations boding evil if they neglect any of their traditional rules regarding the rearing of *tasar* silkworm.

Forest Insect.

Occupation a Punishment.

Sonthals the Hereditary Rearers.

Chinese *Tasar*.

Advantages.

Disadvantages.

All this is quite different with the Chinese *tasar* (*Antheraea pernyi*). It is a native of the warm temperate tracts of China, feeds on oak-leaves (see p. 912), and has been semi-domesticated for centuries. Moreover, it is a bivoltine insect; that is to say, it gives two crops in the year. A domesticated insect that can be reared with ease on a plantation within an accessible locality can hardly help proving more profitable than a wild one, the collection of the cocoons of which over an extensive inhospitable tract of country entails considerable labour and expense. The capabilities of *A. pernyi* in China are as different from those of *A. paphia* in India as y two subjects of inquiry could possibly be. The one is a denizen of a salubrious and invigorating richly cultivated temperate country, the other of enervating tropical jungles infested with disease and animals inimical to human life. The inhabitants of the one country are industrious and energetic, of the other apathetic and enslaved by religious restrictions and obligations that make the collection of *tasar* cocoons distasteful and unpopular. It is one thing to say the insect is "found in the forests of all parts of the Indian continent and to be had for the trouble of collection." It is quite another matter to make that wild insect tractable to the necessities of commerce, or even to overcome the religious prejudices of the agents who have to be primarily employed in the development of the trade.

FOOD-PLANTS OF THE TASAR WORM.—The following are the chief trees on which the Indian *tasar* silkworm feeds :—

Food-plants.

Anogeissus latifolia, *dhaura* (pp. 70-1).
Bassia latifolia, *mahua* (pp. 116-7).
Bauhinia variegata, *kanchan* (p. 121).
Bombax malab cum, *semul* (pp. 168-9).
Careya arborea, *kumbi* (p. 269).
C 'ssa *C* andas, *karaundá* (pp. 270-1).
Celastrus paniculata, *mal kangni* (p. 292).
Chloroxylon Swiete 'a, *billu* (p. 294).
Dodonaea viscosa, *sanatta*.
Eugenia Jambolana, *jáman* (p. 526).

Ficus Benjamina, *nandruk*.
F. religiosa, *wat* (pp. 538-9).
F. retusa, *kamrup*.
Lagerstromia indica, *telinga-china*.
L. parviflora, *bákli* (p. 701).
Ricinus communis, *arund* (p. 916).
Shorea robusta, *sal* (p. 916).
Tectona grandis, *sagun* (p. 1070).
Terminalia Arjuna, *arjan*.
T. belerica, *bhairá*.
T. Catappa, *jangli-badam*.
T. tomentosa, *an*, *saj* (p. 1073).
Zizyphus Jujuba, *ber* (p. 1144).

Crops of *Tasar*.—The *tasar* silkworm has generally two crops, but instead of being bivoltine in its wild state, it is most probably quadri-voltine. According to the Rev. Dr. Campbell, there are often three crops. The cocoons are procured in May and June, from persons who collect them in the jungles. The larger ones are generally female and as much as 8 to 10 cowries apiece are paid for these, while the smaller male ones fetch much less. From these moths emerge, and the 1st crop of caterpillars

s ons.

spin cocoons in September; 2nd crop (a small portion of 1st) emerges in October and spins cocoons about January; the 3rd crop, moths emerge from cocoons of the 1st and 2nd crops about June, which brings us back to the first crop again. A proportion of the September cocoons only emerges in the following August.

Review of
Literature.

TECHNICAL REPORTS.—H. J. S. Cotton, editor of *The Statistical Reporter* (1876, i., 91-3), wrote a paper on the *Development of the Tasar Silk Industry*, in which he reviewed the information available up to that date regarding the reeling, bleaching and dyeing of this silk. A gentleman at Lyons had in 1872 invented and patented, Cotton tells us, a process which he claimed to have solved these difficulties. Sir Thomas Wardle also discovered a process of dyeing *tasar* silk in brilliant colours, and of giving it the lustre of Chinese silk. Mention was at the same time made of a patent taken out by Messrs. Gaddum and Bosshardt of carding the silk of different cocoons. About the same time, Mr. Jules Deveria of Rampur Boalia announced that he had discovered a process of reeling *tasar* on the ordinary filature.

Dyeing.

Carding.
Reeling.

The Government of India in a Resolution, dated November 23, 1875, furnished particulars of the more important investigations that had been conducted both in India and Europe. The chief difficulty depends on an inherent defect in the filaments spun by the worm. It is explained that the silk is produced by the insect from a double spinneret, and that the resulting filaments are not parallel but spirals that touch each other at the exterior points of their curves only, and are held in that position by the natural gum in which exuded. It is to this peculiarity that some of the special properties of *tasar* silk, such as its elasticity, are due. It is necessary that the degree of *croissure* should be exerted to bring the filaments into a round thread. This could only be obtained in fully equipped filatures, and nothing but steam could ensure the uniformly high temperature indispensable. At the period here indicated it was accordingly regarded that the complete reeling of *tasar* silk in the form that would command a large European market could not be accomplished as a village industry. A further Resolution of the Government of India brings the knowledge of this subject up to the date of February 1879; the Resolution and its enclosures will be found reprinted in the *Indian Forester* (1879, v., 77-101). Cotes brought the information up to the date of 1890, and furnished most admirable illustrations of the worm, the male and female moths, and the cocoons. Mukerji (*Handbook of Sericult., India*) afforded much useful additional information regarding *tasar*, but he may be said to have been specially concerned to make the merits of the Japanese and Chinese worms known. Dewar, on the other hand, observes that the mere fact that *tasar* rearing, spinning and weaving are village industries, often combined with agricultural pursuits, gives them an interest to the administrator. The aboriginal or low-caste people who rear the *tasar* worm and gather the cocoons live in the most remote and jungly villages. The weavers form communities in the towns which are not too far from the jungle tracts. Dewar remarks, in his chapter devoted to the history of *tasar*, that the earliest record of its appearance in the Central Provinces "would seem to be that of Chanda district, where in 1775, under the Mahrattas, the monopoly of rearing silk-worms and making *tasar*-silk was farmed out by the ruling power, just as is still done in some Feudatory States." Sambalpur and Chanda are the chief districts in the production of *tasar*, with Raipur and Bilpur taking good second places. During the latter half of the 19th century the Government of India made repeated efforts to extend and improve the production in the Central Provinces, but with little practical results. Dewar reviews the various efforts that were put forth, and his *Monograph* will be found of special value and interest in that respect. Paranjpe (*Ind. For.*, 1902, xxviii., 192-6) gives a sketch of the life-history of the *tasar*-worm in Bhandara.

Yamamai.

Mukerji (*Monog., l.c.*) observes that there are several classes of cocoons which go by the generic name *tasar*. Those recognised in commerce, according to the quality of their silks, are:—(1) The Yamamai cocoon of Japan (*Antheraea yamamai*); (2) the China *tasar* (*A. pernyi*); (3) the *muga* of Assam (*A. assama*); and (4) the Bengal *tasar* (*A. paphia*). All the other wild silks, he tells us, are in Bengal grouped under the name *bharuas*. Of the commercial forms mentioned, the Bengal *tasar* has the greatest length of fibre, though it is inferior to that of the other three. The Yamamai is so highly prized in Japan that, by law, capital punishment may be meted out to any person exporting the seed-cocoons or eggs.

The silk afforded by its cocoons is almost as good as mulberry. The China *tasar* cocoon is smaller than the Bengal, and the average length of its fibre is 550 metres as compared with 700 metres in Bengal. The amount of waste is much greater with the Bengal than the China, though the amount of silk is higher—8 per cent. in Bengal *tasar*, as compared with 5 per cent. in China *tasar*. “The Bengal *tasar* cocoon has a few other advantages over the China *tasar* cocoon. The tenacity of the ‘*bave*’ (i.e. the double fibre as it comes out of the mouth of the silkworm) is 28½ grammes, as compared to 18 grammes, which is the tenacity of the *bave* of the China *tasar*. The elasticity of the *bave* is 21½ per cent. as compared to 19 per cent., which is the elasticity of the *bave* of the China *tasar*. The Bengal *tasar* also loses less of its weight in bleaching; China *tasar* losing as much as 21 per cent. while Bengal *tasar* loses only 11 per cent. The Bengal *tasar* is, however, more difficult to bleach and dye than the China *tasar*.”

China *Tasar*.

Indian *Tasar*.

Indian Results.—Mukerji (*Rept. Inquiry into the State of the Tasar Silk Indust., Beng., 1905*) tells us that he visited all the more important centres of *tasar* production and manufacture and discussed personally with those interested the issues of importance. The report opens with the following:—“The *tasar* silk industry is declining almost everywhere, although the demand for *tasar* cloths has been on the increase in Bengal, owing to the general revival of sericulture in this province, which has brought into prominent notice *tasar* cloths as well as silk cloths.” He then enumerates the chief centres of *tasar* manufacture, and concludes that there are 6,500 families of weavers, or nearly 25,000 individuals, more or less dependent on *tasar*-weaving in Bengal. Of the Central Provinces, he remarks that it is purely a village industry, except in Sambalpur and Bilaspur, but that there are probably not more than 2,500 *tasar* weavers all told. The weavers, he explains, are entirely dependent on a supply of cocoons for the continuance of their industry, but that the rearers are agriculturists who give but a portion of their time to the production of cocoons, and the number so engaged fluctuates very greatly. Roughly, he estimates that the number of persons concerned in *tasar*-cocoon rearing may be about eight times the number of those engaged in *tasar*-weaving. There would be in Bengal, therefore, by that estimate, 200,000 persons, and in the Central Provinces 20,000 persons who obtain at least some portion of their annual earnings from *tasar* silk.

Technical
Reports.

Number of
Weavers.

Mukerji then concludes with numerous practical deductions, amongst which the following may be mentioned:—

Practical
Conclusions.

- (1) That the wild cocoons are the richest in silk.
- (2) That Singhbhum is the district best suited for *tasar*-silk rearing. Further that the wild *barra muga* worm of that district is the best of all, followed by the *muda muga*, also of Singhbhum, then by the *muga* of Mourbhanj.
- (3) That even in the wild state, Chanda and Bhandara cocoons are inferior to those of Raipur, Bilaspur, Sambalpur, and of the Bengal *tasar* districts, while the home-grown cocoons of Chanda and Bhandara are the worst of all.
- (4) That the deterioration is more marked in the case of *banela* than in *muda* cocoons.
- (5) That the main cause of the decline of the industry is the disease known as *grasserie*, which affects weak worms more than strong ones, and worms feeding on low bushes more than those feeding on high branches of trees.
- (6) That *grasserie* being caused by irregularity of season, such as heavy showers following long-continued drought, it cannot altogether be avoided even by the use of good seed.
- (7) That degeneracy of *tasar* worms runs mainly along two lines, inferior cocoons (small size and flimsy in structure) being purposely reserved for seed, owing to the superior cocoons fetching a higher price; and semi-domestication and the use of home-grown cocoons for seed instead of wild ones.
- (8) That the cocoon-rearers are sometimes helpless, as wild cocoons are often not readily found.

Lastly, as measures calculated to revive the industry, Mukerji proposes the establishment of two model *tasar*-rearing nurseries in Bengal; the propagation of *asan* trees (*Terminalia*) in the *tasar* village areas; and the reservation of certain forest tracts for the wild stock only from which the model establishments would periodically obtain fresh seed supplies. With a statement of continuous research and of vigorous efforts, such as that implied by the numerous reports thus briefly indicated, it can be hardly fair to affirm that the backwardness of the Indian industry is a direct expression of the apathy of all concerned.

Revival of
Industry.

Manu-
facture of
Tasar.

MANUFACTURE OF TASAR.—Mukerji (*Monog., l.c., 1903, 104*)

points out that it is strange the cocoons should be gathered in the jungles of Singhbhum, Manbhum, Sonthal Parganas, and even of Assam, and brought down to the filatures of Murshidabad for reeling. To secure improvement the *tasar*-silk reeling and weaving industries should, as far as possible, be estranged from the corresponding mulberry industries, and be developed on their own lines. There should, for example, be no difficulty in establishing *tasar* factories in *tasar*-growing districts, where labour and fuel (both coal and wood) are abundant and cheap. He then adds, "A *tasar* reeling and weaving company organised on European principles and working in the *tasar*-growing districts is likely to have a very prosperous career before it."

Gaya.

In exemplification of these views he then deals with the industry district by district. Of MURSHIDABAD, he says the *tasar* cocoons are reeled in European filatures, chiefly at Bajarpara and Narayanpur factories. Of HUGHLI, Jahanabad Sub-division, he speaks of some 350 families being engaged in *tasar* and mixed *tasar* and cotton weaving. Of BARDWAN, *tasar* spinning and weaving are carried on by some 228 families. A certain amount of weaving is also practised for which yarn is imported. Of MIDNAPUR, he observes that cocoons are found in the jungles, especially at Mourbhanj and Dhalbhum—the hardest kind are preferred. The cocoons are reeled locally and also spun and woven. Of BIRBHUM, he says the *tasar* industry is followed by some 300 families, the cocoons being reeled and the cloth woven locally. BANKURA has long been famous for its silk industry, but the *tasar* manufactures are not very extensive. The most important fabric produced is known as *kethe*. This is made from pierced cocoons, is coarse but cheap. Of BHAGALPUR, the cheap *bafta* cloth is far better known than the *kethe* of Bankura. About 2,000 weavers (both Hindu and Muhammadan) gain a livelihood by producing various *tasar* textiles. The cocoons are imported from the Sonthal Parganas, etc., and sold at Nathnagar at rates of 80 to 250 to the rupee, according to quality—pierced cocoons fetching only from 100 to 400 to the rupee. The yield is about one *tola* of *tasar* silk from 15 to 20 cocoons—and eight to ten *tolas* of *tasar* silk will bring in about a rupee. In the *baftas* the woof is usually cotton and the warp *tasar* silk. Of the SONTHAL PARGANAS, Mukerji says that the cocoons are reared throughout the district for export to Murshidabad—the local reeling, spinning and weaving are practised to some extent, especially in the Godda Sub-division. Of HAZARIBAGH, RANCHI and PALAMAU, he remarks that there is no *tasar* weaving, but that a considerable industry exists in rearing and exporting the cocoons. The pages devoted to these districts will accordingly be found to contain many useful particulars regarding the methods and seasons of the operations concerned. Of SINGHBHUM, he remarks that there are only a few *tanti* (*tasar*) weavers, and the cocoons are reeled by hand by the weavers themselves. The *dhutis* or *saris* so made are largely exported to Dacca and Lower Bengal, and fetch from Rs. 3 to Rs. 4. But if weaving be unimportant, the rearing of *tasar* cocoons is an industry of considerable magnitude in Singhbhum. The *tasar* weaving of MANBHUM is, on the other hand, of considerable value. There were at the last census 12,911 *tantis* or *tasar* weavers, and Raghunathpur is the most important centre. The *tasar* weaving of GAYA is also fairly important, though the cocoons are

no longer locally produced owing to the curtailment of the forests. Of BALASORE, PURI and CUTTACK, Mukerji observes that the industry of *tasar* weaving is not an important one, though the rearing of the worms and production of cocoons are largely pursued.

III. Anther s, Westw.; *Fa. Br. Ind.* (Moths), i., D.E.P., 20; Hugon, *Silk and Silkworms of Assam*, *Proc. As. Soc. Beng.*, 1837, vi., pt. iii., 26-37, t. vi.; Warnford Lock, *Journ. Soc. Arts*, 1880, 510; Geoghegan, 70, 174-4. *Silk in Ind.*, 1880, 151-5; Wardle, *Wild Silks of India*, 1881, 55-61; also in *Journ. Soc. Arts*, May 1885, xxxiii., 676; Stack, *Silk in Assam*, 1884, 5-9; Rondot, *L'Art de la Soie*, 1887; Cotes, *Ind. Mus. Notes*, i., 168-73; Allen, *Monog. Silk Cloths of Assam*, 1899, 3, 10-6; also *Gaz. Assam.*, viii., 158, etc.

This is the *muga* (*munga*) silkworm of Assam, a name said to have been originally given because of the amber colour of the fibre, and hence frequently used to denote any wild silk—thus *eri-muga*, *tasar-muga* and *katkari-muga*. It is met with chiefly in Assam, but its area extends east to the Naga hills, including Sylhet and Cachar, and south to Tippera and the mountains of Burma. It has also been recorded as far to the west as the valleys of Kumaon and Kangra, and a special insect mentioned from Pondicherry, and named *A. perotteti*, has been accepted as a form of *muga*.

istoric Records.—It seems probable that the first mention of this silkworm and of its silk occurs in 1662 in connection with Mir Jumla. But it must long anterior to that date have been known in India, since Tavernier (*Travels Ind.*, 1676 (ed. Ball), ii., 281) makes special mention of the Assam silkworms that remain on trees all the year; and he does not suggest that fact as being a novelty, but rather implies that it was well known. He may, of course, be alluding to the *tasar* silk, but in that case the locality Assam would hardly be correct. The collection of official papers issued by the Bengal Board of Trade in 1819 makes mention of the "*mooga*" being "the most common and plentiful, the thread coarse but winds easily. The *gutis* are sold direct from the forests." This is mentioned separately from "*tussah*," "*terrah*," "*bonbunda*," "*dabba*," "*buggoy*" and "*tarroy*" silks, so that it very possibly was intended to denote the *muga* proper. In the *Dictionary* will be found numerous references to papers by Buchanan-Hamilton, Jenkins, Hugon, Helfer, Brownlow and Stack—all of whom have afforded interesting particulars regarding this silkworm and Assam silk generally.

Do estication.—The *muga* exists in a state of even more complete domestication than is the case with the *tasar*—the eggs are hatched and the cocoons spun within doors, and while feeding on the trees the worms are carefully supervised and protected from their enemies. When they have finished eating they are removed from the trees and carried off to the rearers' houses in order to spin their cocoons. The worm is multi-voltine, has five generations during the year, but of these only two or at most three are used by the rearers. The people of Upper Assam annually import their seed-cocoons from Kamrup for their cold-season and spring crops owing to the fact that the worm soon degenerates in the Sibsagar district, and hence no seed-cocoons are retained from the last brood of the season. This is said to be due to the fact that in Lower Assam the insect is fed mainly on *Litsaea polyantha*, the *sualu* or *howalo*. [*Cf. D.E.P.*, vi., pt. iii., 176; Allen, *Monog.*, l.c. 14-5.]

Food-plants.—The *muga* worm feeds on a fairly extensive series of leaves, the most important being species of laurel, such as the *sum*, *Machilus odoratissima*. But other trees may be mentioned :—*Cinna-*

momum obtusifolium, *Michelia Champaca*, *Symplocos grandiflora*, and several species of *Litsæa*. In Lower Assam it is also largely bred on the *sualu*, *Tetranthera monopetala*. The most important of these food-plants is the *sum* (*Ind. For.*, 1879, v., 35-9, 202-21).

Life-history.—The cocoons intended for breeding are placed in trays and hung up safely in the house. In a fortnight's time during the warm months, and three weeks in the cold season, the insects come forth. The females, recognised at once by their bulkier bodies, are immediately secured by a thread passed round the thorax behind the wings and tied to a short length of straw hooked on to a line stretched across the room. The males are left free, but usually sufficient number consort with the female prisoners. Each female produces 250 eggs in three days. All eggs laid after then are rejected, and the moth dies about the fifth day. The pieces of straw, with their attached eggs, are then taken down and placed in baskets, covered with cloth, and the room in which stored is heated in winter, but kept dark as much as possible. In summer it is not necessary to retain the eggs within doors at all, and the straws may, therefore, be carried at once to the trees, due precaution being taken against undue exposure to sun, rain or dews. Generally, however, the worms are hatched indoors. They pass through four moultings, and, when full grown, measure about five inches long. While feeding, if the leaves get exhausted, the worms are picked off and carried to fresh trees. The worms of their own accord, in fact, descend from the tree and are caught by a trap of straw or plantain leaves tied around the stem, and thus are easily picked up and carried by the attendant to fresh trees. It is said that if placed on a tree the leaves of which have already been devoured, they refuse to ascend. When they have eaten all they desire, the worms are carried off and made to spin their cocoons in the rearers' houses. Trees from three to twelve years old are considered the best; older are avoided, as they harbour ants, and the lichen and moss on their branches impede the rapid movements of the worms. But the greatest enemies of the *muga* are crows, kites and many other birds by day, and owls and bats by night; constant watching is thus necessary, and abundant and continuous employment thus afforded to the young, old and infirm members of the family.

The periods and stages of the insect's life are as follows:—hatching, from 7 to 10 days; feeding, from 26 to 40 days; spinning, from 4 to 7 days; resting within the cocoon, from 14 to 21 days; and life as a moth, from 3 to 5 days. The variations in time indicated are largely a consequence of the season of the year or brood of worm under record. The cocoon is fawn-coloured, large, thin, devoid of the suspensor, so characteristic of the *tasar*; and the short period spent within the cocoon, when taken in conjunction with the more tractable habit of the insect generally, makes this a very much more desirable form of silkworm than the *tasar*. The cocoon is about $1\frac{1}{2}$ inch long and 1 inch in diameter. In colour it is of a golden yellow, but there is usually a percentage of dark cocoons in every brood, for which no satisfactory reason has been assigned.

Reeling and Spinning.—Reeling is simple. The insects within the cocoons are killed by exposure to the sun or by fire. Thereafter they are boiled in an alkaline solution. From 7 to 20 filaments are rolled together between the palm of the right hand, drawn across the thigh, while the left hand works the reeling apparatus. The whole of the silk may be unwound except the innermost layer next to the chrysalis.

The quantity of silk afforded varies according to the brood. The cold-weather insect gives the least, and is accordingly usually reserved for breeding, only the inferior cocoons being spun.

No part of the *muga* cocoon is, however, rejected as useless. The floss plucked off from the outer surface of the cocoon, before reeling is commenced, the shell that remains around the chrysalis, and the cocoons from which the moths have escaped in breeding, are all reserved to be carded and spun, and the by-product thus obtained is called *era* and is often mixed with the *eri* silk—the product of the next species (see pp. 1013, 1021).

Manufacture.—The *muga* silk thread varies according to quality from Rs. 8 to Rs. 12 per seer, *era* or spun thread being sold at half these rates. The cloth woven from *muga* yarn has a bright-yellow colour and a pretty gloss. It stands washing much better than any other silk, keeping its gloss and colour to the very last. It is usually sold in pieces of 5 yards long and 4 feet broad, the price varying from Rs. 1-8 to Rs. 2 per square yard. There is no large market where either thread or cloth can be purchased, but the headquarters of the industry is the district of Sibsagar in Assam, more especially the Sub-divisions of Golaghat and Jorhat. The exports are mainly in thread, which go to Calcutta for local consumption or for export to Persia—it is too dear for the English and Continental markets—the price quoted being Rs. 6 to Rs. 12 per seer. There is no means of knowing the total production, but it has been estimated that the exports come to about 280 maunds a year.

The Champa and *ezankuri mugas* are only the silks of the worm obtained from insects fed on the trees of these names—*Michelia Champaca* for the former and *Litsea citrata* for the latter. Moriani is the chief locality for the *mezankuri* silk. The *champa* silk seems almost quite forgotten to-day, but it was the fine white silk worn by the Ahom kings and nobles of Assam in former times. Buchanan-Hamilton (in Montgomery Martin, *Gaz. of Assam*, 1838, iii., 679-80) speaks of the *medanggori* silk constituting the dress of the higher ranks, “most of which are dyed red with lac but some are white.” Until quite recently it could be said that the *muga* silk was the material of dress with the middle classes of Assam.

The *Eri* Silk, Assam Silk, Palma Christi Silk, etc. The *eri*, *endi*, *arindi*, etc. **Eri.**

It may be said that commercially this silk is obtained from Assam, though Roxburgh and Buchanan-Hamilton speak of it as if in their time it had been confined to Dinajpur and Rangpur. To-day it is found throughout Eastern Bengal in the districts Purnea, Bogra, Jalpaiguri, in addition to Dinajpur and Rangpur. It is also not uncommon in Darjeeling, Nepal, Kumaon, Gaya, Shahabad, Chittagong, Puri, and its cultivation has recently been attempted in Upper India.

The textile sold in India under the name "Assam Silk" is almost invariably the produce of the insect here indicated, though of course *muga* silk is very much more restricted to and characteristic of the valley of Assam. This is the silk with which the poorer people of Assam used formerly to be almost exclusively clad, while the *muga* silk (which in India is often classed as a special grade of *tasar* silk) was that (as already mentioned) employed by the middle and upper classes.

Historic Records.—Perhaps the earliest European record of this silk is of the date 1676, when the agent of Port St. George wrote that large quantities were produced in Goraghat. Milburn (*Or. Comm.*, 1813, ii., 244) gives particulars of what may be accepted as the first European transactions. The cocoons, he observes, are remarkably soft and white or yellowish, and the filament so exceedingly delicate as to render it impracticable to wind off the silk; it is therefore spun like cotton. Roxburgh gives particulars furnished by his correspondents: Atkinson of Jangypur, Glass of Bauglipore, and Creighton of Malda. These names, and the localities with which they are associated, are interesting as forming links that connect the early records. The last-mentioned observer speaks of the worm as reared entirely in the houses of the people. Atkinson refers to his endeavours to reel the cocoons and to his discovery of this being impossible. Hugon and most other authors say the cocoons are softened by being heated in a solution of the ashes of certain plants. They are then opened out by the hand, the chrysalids extracted, the flattened-out cocoons washed, kneaded in the hand, sun-dried, and then crudely drawn out into threads and spun. Brownlow, who half a century later conducted experiments on a large scale, tells us that the cocoons may be softened before being carded by being placed in a solution of cow-dung and water. Most writers mention the circumstance that hot water injures the fibre and that both the carding of the cocoons and the washing of the fabrics should be done, as much as possible, in cold water. Coming to modern times, Sir Thomas Wardle says, "Abandon all idea of reeling *eri* silk; the cocoon is too soft, and the fibres mingled together too irregularly, to afford any hope of successful reeling commercially. Produce it on a large scale, comb and spin it and the success is complete."

Food-plants.—The food-plant of this silkworm, as the name of the insect implies, is the castor-oil or *palma christi* (*Ricinus communis*). There are two forms of that plant grown for this purpose, a green- and a red-coloured. But there are other food-plants, such as *Heteropanax fragrans*—the *keseru*—of Assam; *Ailanthus excelsa*, *Coriaria nepalensis*, *Gmelina arborea*, *Jatropha Curcas*, *Zanthoxylum alatum*, and *Zizyphus Jujuba*. Of these the two first mentioned are by far the most important (see p. 915).

Life-history.—The *eri* worm is multivoltine and reared, as already observed, entirely within doors. The castor-oil plant in Assam and Eastern Bengal is allowed to grow spontaneously in the rearer's back garden or on any unoccupied land in the neighbourhood, and no attention is paid to it. The tending of the worms goes on all the year round, and is accomplished by the females of the household. As many as eight to twelve broods have been recorded, but those actually reared are about half that number. In fact the autumn, winter and spring broods, or those that spin their cocoons in November, February and May, are most highly valued. The broods of June to September are only reared for the purpose of perpetuating the stock. The stages in the life of the insect are as follows:—hatching, 7 to 15 days; feeding as a worm, 15 to 32 days; spinning the cocoon, 3 to 6 days; resting within the cocoon, 15 to 30 days; and lastly, life as a moth, 3 days. The range indicated is due to the influence of the seasons.

Crop.—Mukerji estimates that from an acre of castor-oil plants it would be possible to obtain from 60 to 90 seers of pierced cocoons a year.

The price of these would be about Rs. 60. But in this way it will not pay. It is when grown on odd bits of land and the worms reared and the cocoons spun by the women, during their spare moments, that the industry becomes profitable. Until the price rises materially, it will probably not pay as a separate industry. But as a supplementary crop it is very remunerative, and the insect is more easily reared and is less expensive than the mulberry worm. Since the cocoons cannot be reeled, there is no object in killing the insects within them. In every instance, therefore, they should be allowed to escape. Green *eri* cocoons, that is to say, cocoons with live chrysalids, sell for 500 to 800 to the seer (2 lb.). If they are killed and dried in the sun, 1,500 to 2,500 go to the seer. When the insects have escaped (pierced cocoons), 3,000 to 7,000 go to the seer. In other words, while a maund of pierced cocoons may fetch Rs. 100, the same weight with the chrysalids inside may only realise Rs. 20.

Position of
Industry.

Live Cocoons.
Weight.

Carding and Spinning.—The *eri* cocoon, it is said, has been successfully reeled in Italy, but from time immemorial it has in India been opened out crudely, then spun. No sort of information can be furnished as to the extent of the manufactures nor the probable margin available for export. Mention has been made of a traffic in cocoons from Goalpura to Calcutta of 400 to 500 cwt. yearly. The spun thread, though coarse, is woven into textiles that are exceedingly durable (see pp. 1011, 1021). In fact *eri* silk is stronger than wool, cotton or mulberry silk. But the European trade demands white *eri* cocoons, and this somewhat restricts the supply.

Carding
and
pinning.

Manufactures.—The thread and cloth are largely traded in all over Assam and Cachar, though the effect of the imports of Manchester cotton goods has been to largely displace *eri* as an article of clothing. Hugon speaks of large quantities of the cloth being exported to Lhasa by merchants known as “Kampa Bhotias,” but he adds this trade has entirely died out. Stack says that throughout the whole range of the southern hills, from the Mikir country to the Garo, *eri* thread is in great request for the weaving of those striped cloths in which the mountaineers delight. The Mikirs, Kukis, and Garos cultivate the worm for themselves, but the handsome and durable cloths worn by the Khasias and Santengs are woven of thread procured from the Mikirs. T. N. Mukharji (*Agri. Ledg.*, 1894, No. 19) refers to the fact that within recent years a new market has been found for the cloth, in supplying suits of clothes for the Europeans and Natives of India. The supply, he adds, is not equal to the demand. Efforts have been made with that object in view, in many parts of Bengal and Assam and even in the United Provinces, but so far with indifferent success. A more recent, and in some respects fuller account of the *eri* silk industry, will be found in N. G. Mukerji's *Monograph*. He there gives details of the industry as it exists to-day in Bogra, Rangpur, Jalpaiguri and Maimensingh. Speaking of the increasing demand, he observes that this is now being met by imitation *eri*, made out of waste mulberry silk. He then adds, “At present little skill is brought to bear on the production of *eri* silks either in Assam or in Eastern and Northern Bengal. The spinning might be more uniform and the weaving more varied and artistic.”

INDIAN SILK PRODUCTION AND MANUFACTURE.

In official statistics of filatures and mills, all village industries are disregarded and returns furnished alone of factories, etc., that employ twenty-

ilk
Production.

five or more hands. This gives an unnecessarily low and imperfect conception of the interests involved, since here and there throughout India and Burma there is a fairly extensive village or domestic industry in rearing, reeling and manufacturing, entirely disregarded by official returns. Moreover, recent statistics would seem to mark a serious decline, whereas the explanation of the shrinkage shown is largely the discontinuance to chronicle certain factories.

Official
Statistics.

Filatures.

Filatures, Mills, etc.—According to the latest volume of the *Financial and Commercial Statistics*, there were 75 silk filatures in India in 1904, employing 9,526 workers, all in Bengal. There were also in the same year 11 silk mills, employing 2,964 workers, distributed thus :—in Bengal, 8 mills with 1,465 employees ; in Bombay, 2 mills with 1,299 employees ; and in the Panjáb, 1 mill with 200 employees. According to the *Imperial Gazetteer* (1905, iii., 209) three large silk mills (two in Bombay and one in Calcutta) are worked by steam-power and are almost exclusively concerned in catering for the Burmese market, a trade that was formerly concentrated in Glasgow but is now mainly in the hands of Indian and Japanese manufacturers. “The Bengal factories of to-day largely work up *tasar* silk in place of preparing the *korah* silks formerly turned out by them ; they are owned and managed by Natives and do not employ European machinery. Besides the registered mills and factories, numerous weavers own one or two looms worked by themselves and their families. Silk-weaving seems intimately associated with Gujárat. From one end of India to the other Gujarati silk-weavers may be found, speaking a dialect of Gujarati or using Gujarati names for most of their appliances and for the textiles they produce.”

Steam Mills.

Burmese
Market.

Bengal.

The extent and location of the silk interests may now be indicated :—**BENGAL** (see p. 1019).—This, as already stated, is the great centre of the silk-reeling industry. Formerly a large trade also existed in the manufacture of *corah* (*korah*) silks—plain undyed silk piece goods, the demand for which has fallen off very greatly in consequence of the greater popularity of Japanese and Chinese silks ; but at the present moment the traffic in the Bengal *corahs* seems reviving. [Cf. *Indian Art at Delhi*, 1903, 302-7.] Mukerji says, in his *Monograph*, that with the exception of Chittagong Division, all the other portions of Bengal have a silk-weaving industry. The following particulars may be given of the chief centres :—

Murshidabad.

Presidency Division.—The industry is confined to Murshidabad. Mulberry-growing, cocoon rearing and reeling, as also silk-weaving, are all practised, and the town of Mirzapur produces the most superior fabrics in the whole of Bengal ; but Baluchar and other centres are also famous, especially for artistic and brocaded fabrics. The trade in reeling is mainly concentrated in Berhampur and Jeaganj, and there the wealthy merchants reside. During the last decade the industry seriously declined, both in cocoon-rearing and *corah*-weaving. The census of 1901 shows 41,615 persons dependent on this industry in Murshidabad against 55,142 ten years previously.

Berhampur.

Bardwan.

Bardwan Division.—Silk-weaving is carried on in all the districts. Babu Sukumar Halder gives an interesting historic sketch of the silk industry of Jahanabad, in the Hughli district, during the seventeenth century. In the Bardwan district silk-weaving is mainly carried on in Katwa and Kalna Sub-divisions, but not in Raniganj. The cocoons reared in Midnapur, and even from all parts of Howrah, are utilised in the looms of Chandrakona. In Howrah the silk-rearing industry is of minor value, but the silk-weaving of Bankura is of great importance, even more so than the rearing of cocoons and the spinning industries. It is a curious circumstance that the East India Company should have striven for years to establish Hughli as the centre of their silk industry and have failed to induce the weavers to settle in that district.

Midnapur.

Bankura.

Bhagalpur.

Bhagalpur Division.—In Maldah, cocoon-reeling and silk-spinning are carried on more or less extensively throughout the district, while silk-weaving is con-

centrated at Sahibganj, at Shahpur near Bholahat (silk factory belonging to a French Company), at Sajapur, near the ruins of Gour, and at Maldah. The silk industry of Maldah has in fact slowly but steadily improved during the last decade, and the census figures show 43,498 persons as employed in 1901, as compared with 42,896 in 1891, but this improvement, as in the case of Murshidabad, Rajshahi and Birbhum, has been mainly in the department of weaving.

Maldah.

EASTERN BENGAL AND ASSAM.—Rajshahi Division.—Mulberry cultivation, cocoon-rearing, silk-spinning and silk-weaving are still regarded as industries of very considerable importance. But to feed the European silk factories, cocoons are imported from Maldah as the local supply is insufficient. The chief centre of spinning and weaving is at Mirganj—and the best *matka* silks are turned out at Dakra. The principal trade centre for yarns and fabrics is a portion of the Sadra station of Rampur Boalia. Bogra cocoon-rearing (a greatly depreciated industry) depends entirely on the neighbouring district of Rajshahi for the disposal of its produce.

Rajshahi.

Assam Valley.—Basu (*Agri. Journ. Ind.*, ii., pt. i., 22-32) reviews the results obtained with the experiments to acclimatise the European silkworm in Shillong. This was proposed by Sir J. Bampfylde Fuller in 1904 and has ever since been prosecuted with much energy. It has been proved that the winter colds have proved sufficient to check early and irregular hatching. "Three years' experience has shown that the climatic conditions of Shillong during April and the first half of May, which cover the rearing season, are not unfavourable to the healthy development of the silkworms." But prolonged wet weather is injurious, and it cannot, therefore, be said that the climate of Shillong during April and May is wholly free from danger. Great inconvenience has been experienced in drying the cocoons during the monsoon, which follows closely the rearing season. To safeguard this a drying-case has been used, and apparently with success.

Assam.

Basu points out that a fairly large field exists for the extension of sericulture in Assam. A successful experiment has been performed in Kohima in the Naga hills. Manipur possesses a nascent silk-rearing and manufacturing industry (see pp. 993, 997). There is thus every reason to believe that the European silkworm might be raised in the greater part of the hilly country extending from Manipur on the east to the Garo hills on the west. All over the valley of Assam there are professional silk-rearers, who have only to be taken in hand and educated in the art of safeguarding their worms, in order to secure the foundation for a large and important industry.

Drying.Manipur.
European
Insect.

UNITED PROVINCES OF AGRA AND OUDH.—Perhaps the earliest attempt to organise a modern silk industry in the Dun was made by Capt. Hutton of Mussourie in 1856 (Geoghegan, *Silk in India*, 101-19, 131-2). From time to time various subsequent endeavours were made, and finally Mr. H. G. Ross, Superintendent of the Dun, handed the industry over to Messrs. Lister & Co., Bradford, and it is well known that large sums of money have since 1879 been expended by that Company in their efforts to organise a large and profitable industry. Liotard (*Memo. on Silk in India*, 1883, 24-34) reviews all the experiments performed and the results obtained, and his paper will repay perusal. The story was carried down to 1890 by N. G. Mukerji (*Rept. of a Sericult. Tour in the U. Prov., the Panjab and Kashmir*, 7-14) in his vigorous review of the results attained by Messrs. Lister & Co. The next publication of importance is by Yusuf Ali (*Monog. on Silk Fabrics*, 1900, 9-25). This sets forth the ups and downs in the industry sustained mainly by Lister & Co., and the complete change which has taken place from the *grande mag nerie* to that of tenant rearing. A Savings Bank has also been started by them to protect the rearsers from the money-lenders, and every effort put forth not only to improve the position of the tenants but to simplify the superior methods of silkworm-rearing that they were desired to pursue. To the energy and determination of purpose of the late Lord Darnley (formerly Mr. Lister) has to be attributed the present position of the silk industry of Northern India.

U. Prov.

Lister & Co.

Savings Bank.

PANJAB.—Baden-Powell (*Pb. Prod.*, 1868, i., 161-77) gives a full account of the silk industry of this province during the period of which he wrote. In fact, though many writers have followed his footsteps, very little additional information of any great value has been made public. In 1836 Dr. Gordon conceived the idea of extended silk production. He accordingly planted mulberry trees at Ambala, which still existed in 1858 (Geoghegan, *l.c.* 78-100). It would occupy many pages to enumerate all the experiments that were subsequently conducted. Mr. Cope made a vigorous effort, in 1854-6, to acclimatise the

Mulberry trees.

Gurdaspur.	K hmir insect in Amritsar, where an abundant supply of leaves from standard mulberries were to be had. Passing over many other investigators and adventurers in sericulture, we come to the time when Lister & Co. commenced operations in Gurdaspur and Capt. Bartlett in Kangra. But all this has been already told so fully in the <i>Dictionary</i> that it seems only necessary to refer the reader to that work. [The following publications in sequence of date may assist the inquirer:—Liotard, <i>l.c.</i> 34-46; Cookson, <i>Monog. on the Silk Indust. Pb.</i> , 1886-7; Mukerji, <i>Rept. on Sericult., l.c.</i> , 1890; Hailey, <i>Monog. Silk Indust. Pb.</i> , 1899; <i>Hoshiarpur Dist., Panjab Gaz.</i> , 1904, 135-8.]
Kashmir.	KASHMIR. —Lawrence (<i>Valley of Kashmir</i> , 1895, 367-9) says that Mirza Haidar in his history (A.D. 1536) alludes to the abundance of mulberry trees in Kashmir and to the leaves being used for the food of the silkworm. Adams (<i>Wanderings of a Nat. in Ind.</i> (ed. 1867), 198-9, 269) describes the silkworm industry as seen by him. Drew (<i>Jummoo and Kashmir</i> , 1875, 409) speaks of the silkworms of Gilgit being reared in small quantity and of the worm being smaller than that of Kashmir. Several writers mention a small wild insect seen on the mulberry trees of Kashmir, the cocoons of which were collected and sold. Liotard (<i>Memo. on Silk in India</i> , 1883, 46-55) traces the industry to his time and gives tables of statistics from 1869 to 1881. The effort made in 1869 by the Maharaja Rambir Singh to extend and improve the industry is mentioned by most of the writers on this subject. The cocoons raised in 1876 were valued at 1,70,064 (Indian rupees). But disease appeared, and the industry rapidly declined until taken in hand by Lawrence. In his address to the Society of Arts on April 26, 1896, he tells the story of the efforts that had been put forth to resuscitate the industry. This is followed up by a series of reports and official correspondence (<i>Agri. Ledg.</i> , 1898, No. 10). In his report, dated September 15, 1900, addressed to Sir Adelbert Talbot, Resident in Kashmir, Mr. C. B. Walton, Director of Sericulture, narrates the work accomplished during the year. The crop attained came to 11,019 maunds of cocoons, which when reeled was worth Rs. 7,71,000, which represented 100 per cent. on the cost of production. N. G. Mukerji (<i>Rept. Sericult., l.c.</i> 1-17) gives many interesting details and practical observations. He mentions that he had procured for the State from Signor Susani of Italy, 100 ounces of purely cellular seed of the three best classes of cocoons. Lastly, Sir Thom Wardle (<i>Kashmir, Its New Silk Industry</i> , 1904) tells in some 360 pages the rise and present position of the silk industry of K hmir. He gives particulars of the supply of eggs personally procured, and of the machinery purchased on behalf of the State and which he had taken out to Kashmir and seen established in working order. He also affords details of the subsequent results attained. In a note written by the officiating superintendent of sericulture, Mr. H. D. Douglas, in 1906, it would appear that in 1903 the crop of cocoons was 10,000 maunds; in 1904, 13,000 maunds; and in 1905, 23,000 maunds. The net profit to the State in 1905 came to 1½ lakhs of rupees, and in 1906 to over 3 lakhs. In the year April 1905 to 1906, 600 bales of silk of 150 lb. weight were reeled. The price realised at the beginning of the year was about 12s. a lb., whilst later 15s. were obtained. Last year 10 looms were started to produce cloth in competition with Japan, and, these proving successful, 200 more looms had been ordered and arrangements made for these to be in working order by June 19, 1906. Thus the revived industry bids fair to be of the utmost value not to Kashmir alone but to the British Empire.

Afghani- stan.	SIKKIM, NEPAL AND KUMAON, BALUCHISTAN, ETC. —Very little information exists regarding the attempts that have been made to establish a regul silk industry on the Himalaya except at Dehra Dun, to which reference h already been made. Further to the west in Afghanistan and Baluchistan there has always existed a small industry. Thus Moorcroft (<i>Travels</i> , 1841, ii., 416) mentions that the town of Yang Arekh Bokhara is supported chiefly by its filatures of raw silk. There are two kinds of silk, white and yellow, exported to Kabul and Peshawar. This is the survival of the early traffic from Central Asia to India (repeatedly alluded to in connection with Khotan) conveyed down the Indus river to Bombay and Surat.
aluchi- stan.	Speaking of Baluchistan, it may be observed that the present industry is due very largely to Mr. Rogers, who, at his own expense, conducted in 1901 experiments at Kirani near Quetta. The silk produced was so favo ably spoken of that efforts have been since put forth by Government to extend the adventure, the locality selected being Mustang in Khelát, where many villages were known to possess large numbers of mulberry trees. His Highness the Khan
Mustung, Khelát,	

(under the advice of Major Showers, Political Agent) he entered enthusiastically into the scheme of a new industry for his people. In April 1905 Showers wrote a long official report that not only gives the history of the Khelât experiment but the results hitherto attained, and the opinions of the brokers, as also of Sir Thomas Wardle, on the silk produced. These all combine to confirm the high expectations entertained regarding the future of the Baluchistan and Khelât silk industry.

BOMBAY.—The silk manufactures of Ahmadabad were famous alike during the time of its own kings and of its Muhammadan Viceroy. The chief excellence lay in the bright colours of the plain stuffs and the strength of the brocades. (For Ovington's account, see pp. 995, 1020). Under the Marathas (1755–1817), however, Dunlop wrote in 1817 that it was taxed when raw, as it passed through every process of manufacture, and again when ready for sale, and was thus so weighted that in competition with foreign silks, the local manufacture almost ceased to pay and all but died out. Geoghegan (*L.c.* 35–55) says that the first attempt at silk-rearing in Bombay was made in 1795 by Dr. H. Scott. Hove, the cotton expert, lived with Scott, but in his *Tours for Scientific and Economical Research*, written in 1787–8, no mention is made of silk. In 1679 the Governor of Fort St. George recorded in his Diary, of 5th December of that year, his having come across Gujarati silk merchants buying silk for Ahmadabad. It is thus highly likely that the raw silk exported from Western India was to some extent at least Bengal silk, seeing that there is no evidence of silk-rearing having been successfully established in Western India until well into the 19th century. As just stated, frequent mention has been made of a silk supply drawn to Western India from Central Asia, the route being down the Indus. The earliest record of cultivation in Bombay Presidency is in 1823, when the worm was conveyed from Mysore to Dharwar. Shortly after (in 1827) Mr. Giberne planted his garden at Dhulia in Khandesh and Signor Mutti opened out his silk farm at Poona in 1829. During the first year of British occupation of Ahmadabad (1818) the import of raw silk amounted to 11 tons (300 Indian maunds), during the second year it came to 37 tons, and in 1847 stood at 109 tons. Since then the trade has witnessed extreme fluctuations. Numerous explanations have been offered, such as the rise of the cotton traffic—both local production and foreign imports; changes of fashion, more especially the decline of the demand for brocades by the Kathiawar chiefs; and lastly the growth of the trade in Chinese and Central Asiatic woven silks.

There are three chief classes of silk goods produced in Ahmadabad, viz. plain silks, brocades, and silk prints. The plain goods are also largely produced in Surat, and the markets for these are Kathiawar, Rajputana, Central India, Bombay, the Deccan, the Central Provinces and the Nizam's Dominions. The brocades, as also cloths of silver and gold, are much less used for robes nowadays than formerly, but are in demand for upholstery and elephant and other trappings.

Surat has for long years past been largely concerned in the supply of silks to Burma, and a Native of Surat, seeing the advantage of proximity to the Bengal silk supply and the facility of export to Rangoon, some years ago organised a silk factory in Calcutta to be run exclusively for the Burmese market. But for many years past the demand by Burma for Indian silks has shown a decided tendency to decline, and an inquiry was instituted as to the cause. It was pointed out that in the first instance the silk-weavers of Surat were primarily responsible, in that yielding to the recommendations of Native merchants in Rangoon, they had gradually lowered their price by reducing the quality until it was recognised in Burma that the locally manufactured silks, though more expensive, were infinitely more lustrous and the colours and patterns more in accord with the prevailing fashion. It was also pointed out that the advances of European commerce and the necessities of the people had led to a substitution of cotton for silk goods.

MADRAS.—Brandt (*Résumé of the Rec. of the Mad. Govt. relative to the Cult. of Silk in the Pres.*, Oct. 1871) says that no mention occurs of silk in connection with Madras prior to the year 1791—a statement that is hardly correct (see p. 1019). Tippu Sultan appears closely associated with the rise of the modern industry. A Native of Trichinopoly was by him sent to Bengal to learn the silk trade. But there must have existed an industry prior to that date, since we read of a present made to an Englishman, in 1793, having consisted of "kincoobs" made at Trichinopoly. Dr. James Anderson, Physician General at Madras, established in 1771 a plantation of 5,000 white mulberry bushes from Hyderabad stock at Nungumbaukum—a suburb of

Madras—and in December 1790, after many failures, succeeded in acclimatising the Bengal worm. It would seem that this insect, subsequently conveyed back to Bengal, may have given origin to the name *Madras*, the alternative name for the *nistri*—the *Bombyx cressi* of Hutton. Dr. Anderson urged that the Peninsula, owing to its more equable temperature, had great advantages over Bengal. In consequence, a vigorous effort was made by the Madras Government to distribute Dr. Anderson's acclimatised insect to all parts of South India deemed likely to prove suitable new areas, and every encouragement was given to extend mulberry cultivation. Collectors, surgeons, paymasters, etc., became superintendents of Government plantations all over the Presidency. About this time Dr. Anderson reported a successful experiment to improve the Bengal silkworm, 10½ grains of silk being obtained as against 6 grains, the average outturn in Bengal. Cocoons were wound on the Piedmontese reel and ultimately a brilliant white silk was obtained. But it soon began to be believed that Dr. Anderson had taken a too sanguine view of the possibilities of the Madras Presidency in the rearing of silk. All parts of South India were not alike suitable, and a uniform climate, that might admit of breeding throughout the year, was soon realised as by no means a desirable state of affairs. This story of the Madras experiments is very largely that also of many other enterprises in India—ignorance of the conditions upon which alone success depends being the foundation of a superstructure of failure and disappointment greatly calculated to retard legitimate endeavours. The Madras Government spent £20,000 in four years, and a further sum of Rs. 78,736, for the filature constructed at Vellavedu. They shortly after advertised their plantations and property for sale, but obtained no offers.

Notwithstanding the failures and disappointments in the acclimatisation of the silkworm and the establishment of a silk-reeling industry, the manufacture of silk and satin made considerable progress in the Madras Presidency. And beyond the Presidency the silk brocades and the plain silks of Mysore are famous even to the present day. A century ago Buchanan-Hamilton (*Journ. to Mysore, etc.*, i., 208, 222; ii., 263) gave an account of the industry that to this day hardly been excelled for its fulness and thoroughness. Persons desirous of studying the subject of silk in South India could not do better than begin their inquiry by perusing Hamilton's account.

MYSORE.—In Mysore and Travancore greater success was attained than in any part of the Madras Presidency proper. In 1849 Surgeon Smith published a report of the silk experiments of Mysore from the date of its introduction by Tipu Sultan to the date of his report. Coming down to recent times, the story of failure has to be replaced with a record of success. The late Mr. J. M. Tata started an experimental silk-rearing farm in Bangalore with a view to resuscitate the industry. In 1897 he personally visited Bangalore and chose the land for his plantation and rearing-houses. He then sent off to Japan to obtain the services of a superintendent and a selected number of trained operatives, both men and women. It was soon ascertained that the tableland of Mysore approximates climatic conditions very closely to that of the warm zone of Japanese silk culture. The services of Mr. T. Odzu were in 1899 procured as manager and the farm was started a little beyond the Basavanagudi extension at the village of Yediyur. A similar experiment was started by Mr. Partridge at Yellahanka near Bangalore. Henceforward we read of steady progress in the Tata Farm, the Mysore authorities having made it a grant of Rs. 3,000 a year in return for obtaining permission for its utilisation as a sort of school where the Japanese methods of growing the mulberry and rearing the insects might be taught to the people of Mysore. And it may be added that it soon exercised even a wider influence in connection with the proposed new silk farm of Pusa in Bihar. The Mysore farm was also visited by Major Showers, in order to study the methods pursued. That officer has since organised a silk industry in Khelât (official letter dated April 29, 1905), and says, "I may note here that about the best Indian silk that has reached London yet, is that produced at the Tata experimental silk farm at Bangalore. A sample of this silk was shown me by Mr. Frank Durant (Durant, Bevan & Co.), and he advised our taking that as a model at Mastung. This silk realised as much as 17s. a pound." Such high testimony is thus fully expressive of the great success attained by the Tata Farm.

THE SILK TRADE OF INDIA.

Trade.

EARLY RECORDS OF INDIAN SILK TRADE.—Varthéma (*Travels*, 1510 (ed. Hakl. Soc.), 38) speaks of the silk of Bengal being conveyed to Europe. In a

further passage he discusses the cotton and silk goods of Cambay. In a third, makes mention of the silk being made in large quantities at a place identified as having been Masulipatam. These three statements thus exemplify the three great centres of the early silk trade of India. Sir George Birdwood and Mr. W. Foster published, in 1893, *The First Letter Book of the East India Company*, or a register of the official correspondence from 1600-19. We there read, in the Commission granted to the commander of the Company's second voyage (1605), of provision being made for the purchase of raw silk, but there is nothing to show that the entry in question denotes that the silk was to be procured from India. In subsequent commissions of other ships, such as of the date 1609, special mention was made of the Chinese and Persian silks. The former are spoken of as Lamking (Nanking) and Canton. Persian silk was sent in 1617 to Surat in exchange for sugar and other Indian commodities. It would seem that the Company's first efforts at silk manufacture were made in Surat, though everything points to the raw silk having had to be carried to the manufacturers of that town (see pp. 995, 1017). Mr. W. Foster, in a series of volumes entitled *Letters Received by the East India Company, 1602 to 1619*, affords many useful additional historic facts regarding the silk trade of India. We there learn that, disregarding letters that deal with China, Japan, Malay, Siam or Straits silks, one of the earliest mentions of Indian commercial silks occurs in a letter from Cambay, dated 1614. It is there stated that silk used formerly to be brought to that city from the interior. One of the earliest references to Bengal silk occurs in a letter from Sir Thomas Roe, written at Ajmir, December 1616, in which he discourses against the proposal then made to found special factories in order to purchase Bengal silks. He says that these are to be "had cheaper at Agra." "I am of opinion your residences are sufficient and best chosen as they are." He then adds that there exists "Silk of Bengala plenty at reasonable rates" (*E.I.C.*, l.c. iv., 250). Subsequently, in 1619, a letter was issued from the factors at Surat to those at Masulipatam, in which an acknowledgment is made of "Musters of Bengala silke." Foster (*The English Factories, 1618-21*, 153) furnishes a letter from Masulipatam, in which the following occurs, "I am in good hope after some small time to furnish you with good quanteties of that sort of Bengala silke which Lawrence Walso first, and Robert Young after, shewed you musters of in England." In a further letter, of date 1620, we read of Robert Hughes having been deputed from Surat and Agra to organise a factory at Patna. He purchased a maund of "serbandy" cocoons, for he adds it is "the cheapest and surest dealing to buye the serbandye and wynde it of myselfe." Further on, doubt is thrown on the advantage of a filature at Patna, seeing that the silk cocoons had to be conveyed from "the cittye of Mucksoudabad (Murshidabad) where it is made, which would bee worth bothe labor and charge, for wee are assured that there it may be provided in infinite quanteties at least twenty per cent. cheaper than in anye other place of India, and of the choysiest stufe, wounde off into what condition you shall require it, as it comes from the worme; where are also innumerable of silk wynderes, experte workmen, and labour cheaper by a third than else where" (*l.c.* 229-30). Bernier (*Travels, 1656-8*, 439-40) says, "There is in Bengale such a quantity of cotton and silks, that the kingdom may be called the common storehouse for those two kinds of merchandise, not of Hindoustan or the Empire of the Great Mogol only, but of all the neighbouring kingdoms and even of Europe." Tavernier (*Travels in Ind. 1676* (ed. Ball), ii., 2-3) tells us that in his time Kasimbazar ("Cosenbazar"), a village of the kingdom of Bengal, furnished about 22,000 bales of silk annually, each bale weighing 100 lb. "The Dutch," he continues, "generally took, either for Japan or for Holland, 6,000 to 7,000 bales of it and they would have liked to get more, but the merchants of Tartary and of the whole Mogul Empire opposed their doing so, for these merchants took as much as the Dutch, and the balance remained with the people of the country for the manufacture of their own stuffs. All these silks are brought to the Kingdom of Gujarat, and the greater part come to Ahmedabad and Surat, where they are woven into fabrics." "The crude silk of Kasimbazar is yellow." Bernier says, "The Dutch have sometimes seven or eight hundred Natives employed in their silk factory at Kasimbazar, where, like many other merchants employ a proportionate number."

manner of silken goods. The practical silence of Muhammadan writers on the subject is, however, significant, and tends to the conclusion that until the advent of the East India Company, little progress was made toward extending and improving the Native industry. Of the European traders, the Dutch were probably the first to find their way to the Bengal silk districts. It seems, in fact, to have taken the British the greater part of a century before their knowledge of the Bengal production took definite shape and they had assumed direct control. Most of the early books of travel, in discussing silk, speak either of the silks of Gujarat or of Masulipatam. Mandelslo (*Travels*, 1638, in Olearius, *Hist. Muscovy*, etc., 83) discusses the "Cotton and Linen Cloaths" and "Silk Stuffs" either conveyed to Surat or worked up there. In fact the British merchants seem to have striven hard to make Surat the chief centre of their Indian silk traffic, though they do not appear to have ever made the attempt to rear the silkworm there nor to build filatures at Surat. They carried the raw silk from Bengal to their looms. It is, therefore, surprising how Ovington could have written his most admirable account of the silkworm to which reference has been made above (p. 995).

Sir Henry Yule, in his Biographical Sketch of Sir Streynsham Master (*Diary of William Hedges*, ii., app., cccxxvi.), gives passages from a letter by Master descriptive of Kasimbazar, in which he speaks of all the country being planted with mulberry trees. Sir Henry fixes the Company's establishment of an agency in Kasimbazar at 1658 (*l.c.* iii., xciv.), though they had occasional agencies there as early as 1653. The reader will find much interesting information regarding the establishment of the East India Company's silk industry in the late Mr. C. R. Wilson's *Early Annals of the English in Bengal* (i., 39, 55, 375-8, 394; ii., 196, 228, 369).

EXPERIMENTS AT IMPROVEMENT OF INDIAN SILK.—Between the dates mentioned for the establishment of the agencies and the records of the Company's erection of filatures in Bengal, there is a gap of a century of which we know little more than has been indicated. In the volume of *Reports and Documents* published by the East India Company in 1836 (to which repeated reference has already been made) much interesting information will, however, be found. It is there stated that the trade of the Company in raw silk was inconsiderable in extent before the middle of the last century. The chief places then producing silk were "Cossimbazar, Commercolly and Rungpore." The class of silk procurable was described as *country wound*. But it was freely admitted that the fault of that silk was its inequality, some portions being single, others double or even quadruple. Accordingly, in 1757, Mr. Richard Wilder, a gentleman trained in every department of the silk industry, was sent to Bengal to examine into the cause of the defective quality of Bengal raw silk. Wilder continued in India until his death in 1761, and was enabled to lay the foundation of great improvements in the winding of silk. Mr. Joseph Pouchon was appointed to succeed Wilder, and he claims to have so improved the reeling that Bengal silk became equal to that of Italy or any other country. In 1768 the Court of Directors advised the Government of India that it was to the increase in raw silk that they looked chiefly for the means of bringing home their revenue. Subsequently the Court advised the Government that although there was no branch of their trade which they more ardently wished to extend than that of raw silk, still they could not think of effecting so desirable an object by any measures that might be oppressive to the Natives, and, therefore, no compulsory methods were to be adopted to increase the number of the silk-winders. With regard to planting mulberry, it was suggested that deductions from rent should be made on lands planted with it so as to amount to a bounty by rendering it more profitable than any other article of culture.

But complaints continuing to be made by the purchasers of Bengal silk, it was resolved to adopt the methods of winding practised in the filatures of Italy and other parts of the Continent. For this purpose the services of experts (both English and foreign) were secured and located at the Company's agencies. For example, Mr. James Wiss, a native of Piedmont, was stationed at Commercolly with four Italians under him, engaged as drawers and winders. Mr. J. Robinson was stationed at Rangpur with three Italian experts under him. While Mr. W. Aubert, with three expert reelers from Languedoc, was appointed to another *aurung*, but Aubert died at Madras in 1771, and thus never reached Bengal. The first report on the silks produced was to the effect that Mr. Wiss had succeeded to admiration in drawing a tolerable silk from the most ungrateful

THE EAST INDIA COMPANY

ILK
Trade

of cocoons, the sickliest of worms, and under the most unfavourable season possible. This led to recommendations to improve the stock, both of the worms and the mulberry, and a long correspondence ensued, in which ultimately Drs. Roxburgh, Wallich and Lush took part, and which culminated in the attempt to adopt the Italian standard method of growing the plant in place of the Bengal bush system.

Standard
Cultivation
Adopted.

The great difficulty in conveying live eggs from Italy to India seems to have suggested two alternatives:—1st, to get Italian eggs from St. Helena as a half-way house; and 2nd, to obtain China stock. In 1771 eggs were accordingly procured from China, and at the same time the Chinese mulberry was brought to India. In 1774 it was reported that the Italian method of reeling had been so far successfully introduced that it promised in a reasonable time to fulfil all expectations. Wiss retired from India in 1776, but was appointed by the Company to a post in England by which he was enabled to afford much valued advice to the manufacturers in India. It would occupy too much space to follow the course of events farther. The purpose in view has been served, namely to exemplify the enlightened action of the East India Company and the far-reaching efforts which they expended in their endeavours to improve and extend the Indian silk production. It need only, therefore, be added that the Board of Trade in Calcutta established in 1832 an experimental filature in Howrah for the purpose of instituting comparisons and experiments, with a view to improve the manufacture of raw silk. This was intended to guide the operations of the Company's Residents in the chief silk-producing districts.

Italian Eggs.

China Eggs.

E.I. Company's
Efforts.

Experimental
Filature.

Under the fostering care, therefore, of the East India Company, the Indian silk trade prospered greatly. During the early years of its existence it had only Turkey, China and Japan to contend against. Gradually, however, the efforts to acclimatise the silkworm in Italy and France, and to engraft sericulture among the regular industries of these countries, were crowned with success, and India had thereby to face formidable rivals. The East India Company gradually also found new and more immediate outlets for their enterprise, and silk, in consequence, passed into the hands of private persons. Discouraged by the lessening demand for Indian raw silk, the industry fell behind and degenerated until it was held that Indian silk could not compete with that of Europe.

Formidable
Rivals.

Many writers had reported that the cocoons of the silkworm that feeds on the leaves of the castor-oil plant could not be reeled, but that the Natives of Assam carded these and spun them like cotton (see pp. 1011, 1013; also Roxburgh, *Trans. Linn. Soc.*, 1804, vii., 45). Up to 1858 no advantage was taken of that fact in Europe, but in the year mentioned, the discovery was at last made in England that the silk waste and wild silks of India might be utilised in the manner mentioned. A new demand arose for these materials, and, in consequence, a complete change took place in the nature and location of the Indian silk trade. The waste silk of the village reeling business found a ready sale. A market was created for wild silks, and an export trade made its appearance in official returns under the heading of waste silk. Moreover, the reeled silk of India, about the period indicated, was recognised as possessing special features of its own for which a distinct demand existed. To Sir Thomas Wardle is due the credit of having urged, and successfully accomplished, the renewal of the efforts to improve the methods of reeling. He pressed for the introduction of better reeling machinery, even although M. Gallois had pointed out that he had some time previously introduced the *Tavalette consono* machine, and found that the silk made by the ordinary process was quite as good. It has, however, been freely admitted that great improvements might be carried out by more care in reeling on the lines advocated by Wardle.

Carding of
ilk.

Renewed Efforts.

FOREIGN TRADE.—Milburn (*Rise and Prog. of the Silk Trade*, in *Or. Comm.*, ii., 244-60) gives the early returns of India. The first consignments of wound silk from India to England were made in 1772, and during the five succeeding years the returns of that nature averaged 180,000 lb. In 1785 they came to 324,307 lb.; in 1795, to 380,352 lb. About this time the Company's purchases were made by contract, and it is recorded that a loss of £884,744 had been sustained. The total imports of Great Britain in raw and thrown silk were in 1773 returned as 777,373 lb., of which, under the heading of raw silk, were 145,777 lb. from Bengal; 203,401 lb. from China; 187,099 lb. from Italy and Turkey; and 6,190 lb.

from other parts; while under thrown silk, the total receipts were 234,906 lb. Twenty years later the corresponding figures were, total imports 1,261,963 lb., of which (raw silk)—Bengal supplied 736,081 lb.; China, 165,435 lb.; Italy and Turkey, 110,276 lb.; and other parts 8,216 lb.; with fully one quarter of the total consisting of thrown silk, viz. 241,954 lb. But shortly after a complete revolution took place. The silkworm was acclimatised in both France and Italy, and immediately thereafter the demand for silk in Europe not only increased very rapidly but the demand for the Indian fibre declined. The returns of the exports of raw silk from Bengal to England about this time began also to manifest a new feature, viz., it was referred to two sections, Company's and Private exports. In 1805 the total exports came to 835,904 lb., of which 460,303 lb. were made by the Company. In 1825 the total exports were 919,436 lb., of which the Company's share came to 699,230 lb. In 1835 the total exports of raw silk came to 727,535 lb., of which the Company exported 721,509 lb.

From 1857, when the utilisation of waste silk began to be understood and practised in Europe, the exports of India changed their character. The returns rapidly manifested a decline in value, due largely to the growth of the traffic in *chasam* (waste silk) and cocoons, in place of the reeled silk of former times. In 1867-8 the exports of raw silk from India were 2,226,201 lb., valued at Rs. 1,55,32,290. In 1877-8 the total exports from India were 1,512,819 lb., valued at Rs. 70,35,493; in 1880-1 they were 551,000 lb. reeled silk, plus 788,000 lb. waste silk and *chasam*, valued at 55 lakhs. Thus in twenty years from 1867-8, the exports declined from a valuation of 1½ millions to ½ a million sterling. In 1900-1 the figures were 560,000 lb. reeled and 1,031,000 lb. waste, with a total value of 51 lakhs.

RAW SILK.

It is not always possible to refer the traffic in Raw Silk to the two important sections Wild and Domesticated, but where this can be done, the proportion which the former bears to the total will be exemplified.

Exports.—The following table exhibits the Foreign Exports for the past seven years, arranged under the three chief classes, viz. Reeled Silk, Chasam or Waste, and Cocoons.

Years.	Reeled.	Chasam.	Cocoons.	Total.
1900-1	lb. 559,776 Rs. 43,02,707	1,030,523 8,09,619	13,976 9,731	1,604,275 51,22,057
1901-2	lb. 727,651 Rs. 57,53,220	1,165,754 8,49,948	42,356 31,041	1,935,761 66,34,209
1902-3	lb. 681,852 Rs. 55,24,418	1,240,689 9,66,154	67,281 57,181	1,989,822 65,47,753
1903-4	lb. 624,064 Rs. 52,51,669	1,136,566 9,89,979	101,636 1,00,820	1,862,316 63,42,468
1904-5	lb. 506,318 Rs. 42,49,181	751,355 6,40,957	85,990 79,837	1,343,663 49,69,975
1905-6	lb. 578,450 Rs. 47,32,832	1,131,960 8,43,059	68,906 63,788	1,779,316 56,39,679
1906-7	lb. 777,654 Rs. 59,38,726	1,095,193 8,57,700	70,591 68,592	1,943,438 68,65,018

Of these amounts, the WILD SILKS were as follows :—In 1900–1, the exports of reeled wild silks were 62,693 lb.; in 1901–2, 16,884 lb.; in 1902–3, 3,919 lb.; in 1903–4, 10,494 lb.; in 1904–5, 19,287 lb.; in 1905–6, 26,904 lb.; and in 1906–7, 23,990 lb. The traffic in reeled wild silk has thus fluctuated very greatly. Of *chasam* or waste, the figures given are much higher, and seem to have been on the whole increasing, though in 1904–5 a shrinkage occurred. The figures were in 1900–1, 447,488 lb.; in 1901–2, 492,113 lb.; in 1902–3, 626,977 lb.; in 1903–4, 727,545 lb.; 1904–5, 350,514 lb.; in 1905–6, 634,593 lb.; and in 1906–7, 463,440 lb. So also the traffic in cocoons seems to have marked an expansion, though a shrinkage occurred in 1905–6. Let it be observed, however, the exports of this nature are almost entirely wild cocoons. The returns of wild cocoons exported were in 1900–1, 13,976 lb.; in 1901–2, 32,940 lb.; in 1902–3, 53,125 lb.; in 1903–4, 87,952 lb.; in 1904–5, 80,540 lb.; in 1905–6, 46,725 lb.; and in 1906–7, 36,965 lb.; which figures, it will be seen, leave very small balances annually that have to be accounted for as being domesticated cocoons.

Turning to the provincial transactions, it may be pointed out that practically the whole of the reeled silk exported from India goes from Bengal. Of the *chasam*, it may be said that two-thirds go from Bengal and one-third from Madras, the other provinces contributing negligible quantities. So also of the traffic in cocoons, two-thirds go from Bengal and one-third from Madras. Thus it will be seen the exports from the province of Bengal are by far the most important, since, as a rule, they amount to three-fourths of the total. Following Bengal come the Madras ports, which usually contribute from a fifth to a fourth of the total foreign exports. As manifested by the returns of railborne traffic, these Madras exports must be Mysore silk carried to the Madras port towns by rail, and then exported to foreign countries. But if anything, the Madras traffic seems to be declining, while the exports from Bombay are expanding. In 1900–1 the Bombay exports stood at 10,091 lb., while in 1906–7 they had expanded to 233,774 lb. From the returns of railborne traffic, the raw silk that drains into Bombay town (from which the foreign exports are largely made) appears to be mainly Panjáb silk, or silk conveyed into the Panjáb from across its land frontier—doubtless to some extent Kashmir silk. Of these foreign exports about three-fourths go to France and approximately one-fourth to the United Kingdom.

I ports.—Perhaps the most significant feature of this aspect of India's foreign silk trade is the circumstance that more raw (reeled) silk is imported by Bombay and Burma than is exported by Bengal. The figures for the years 1900–7 have been :—1900–1, 2,535,377 lb., valued at Rs. 1,01,69,402; in 1901–2, 2,128,483 lb., valued at Rs. 80,96,200; in 1902–3, 1,639,189 lb., valued at Rs. 55,16,149; in 1903–4, 1,544,315 lb., valued at Rs. 59,29,527; in 1904–5, 1,858,709 lb., valued at Rs. 73,41,121; in 1905–6, 1,645,696 lb., valued at Rs. 71,19,049; and in 1906–7, 1,422,467 lb., valued at Rs. 56,80,273. Of these quantities practically the whole comes from China and the Straits, the former furnishing about four-fifths of the supply. It has often been pointed out that this large import trade is mainly a consequence of the cheap freights by the return opium steamers to Bombay. But there would seem no doubt that Bengal for a century or more had failed to meet the demands of Western India.

Imports.

Reeled Silk.

From China and the Straits.

Taken by
Bombay.

The Bombay demand was, however, the incentive for the Gujarati silk merchants and weavers permeating the whole of India and forming the colonies that exist to-day all over the chief silk-producing localities of the Empire. It is needless, therefore, to add that out of the imports, Bombay takes by far the major portion, only about one-seventh going to Burma, while the other provinces take practically no share in these imports.

Bengal and
Bombay.

Thus while Bengal is the great producing province, Bombay is the chief distributing centre. By rail and river the Chinese silks brought to Western India are carried not only through the Presidency of Bombay, but very largely to the Panjáb and even to the United Provinces. Hence it may be said that while Bengal is the chief producing province, the Panjáb is the chief consuming province of India.

Bengal and
Panjáb.

Re-
exports.

Re-exports.—It only remains to briefly indicate the re-export trade, practically the whole of which goes from Bombay, and is, in consequence, Chinese silk. The quantities of foreign silk re-exported during the period of 1900-7 were as follows:—1900-1, 97,519 lb., valued at Rs. 1,89,475; 1901-2, 59,941 lb., valued at Rs. 1,46,265; 1902-3, 85,249 lb., valued at Rs. 1,62,279; 1903-4, 68,131 lb., valued at Rs. 1,40,828; 1904-5, 54,522 lb., valued at Rs. 1,48,729; 1905-6, 69,330 lb., valued at Rs. 1,35,045; and in 1906-7, 105,288 lb., valued at Rs. 3,78,860. These re-exports go mainly to the United Kingdom and Arabia.

MANUFACTURED SILK.

Manu-
factures.

Repeated reference has been made to N. G. Mukerji (*Monog. Silk Fabrics of Beng.*, 45-82); his chapter on fabrics will be found to give every possible detail regarding the rise and present position of the Indian industry, the class of goods manufactured, and the extent of the trade. He mentions, for example, the Murshidabad silk manufacturers turning out many different classes of goods, such as gown-pieces, *corahs*, silk-muslins, handkerchiefs, *mathas*, imitation Assam silk, etc. The last mentioned was specially introduced by Mukerji himself as a relief measure, but the success attained has "given rise to a hope that under a fostering care the silk-weaving industry of Bengal may be developed in other directions also." Speaking of the *corahs*, Mukerji observes that "these are the cheapest silk fabrics which form the staples of export to Europe, where they are used mainly for lining purposes. *Corahs* are generally woven 7 yards by 1 yard, and sold at a rupee (= 1s. 4d.) per square yard. They are made out of unbleached and untwisted thread, and bleached in the piece after they are woven. *Corahs* are also woven 10 yards by 42 inches, like ordinary gown-pieces, and worn as *saris* by widows. Like gown-pieces, *corahs* are valued by the number of warp threads (called *sháná*), 2,400 warp threads per yard making the best gown-pieces and *corahs*, while 1,200 or 1,000 warp threads per yard make the poorest gown-pieces and *corahs*. The price of *corahs* varies from 6 annas to Rs. 1-8 per square yard." In the *Review of Trade of British India* (1904-5, 38), the statement occurs: "The exports have steadily diminished during the last five years, the decrease compared with 1903-4 being 12 per cent., and what was once a trade of some importance is rapidly approaching insignificance." This has reference mainly to the decline in the exports of *corah* silks, in which there seems some prospect of a revival. But at present the exports from India are "chiefly

Gown-pieces.

Decline.

TRAFFIC IN MANUFACTURED SILK

ILK
Trade

of tissues woven in Bengal from indigenous silks, for the Bombay mills employ imported silk and weave principally for the home markets."

Exports.—These again may be best arranged in tabular form under the chief classes—piece goods, silk goods mixed with other materials, thread, and other sorts.

Year.	Piece Goods.	Mixed.	Thread.	Others.	Total Values.
1900-1	yds. 1,175,924 Rs. 10,96,770	152,367 1,56,197	lb. 175 Rs. 630	60 850	12,54,447
1901-2	yds. 854,092 Rs. 8,90,549	196,072 1,61,507	lb. 257 Rs. 2,022	81 616	10,54,694
1902-3	yds. 819,324 Rs. 8,30,432	108,951 1,15,095	lb. 39 Rs. 314	1,036 3,010	9,48,851
1903-4	yds. 677,225 Rs. 6,51,720	151,835 1,80,169	lb. 3 Rs. 30	44 750	8,32,669
1904-5	yds. 535,182 Rs. 5,66,868	162,389 1,80,169	lb. 264 Rs. 30	80 1,214	7,48,281
1905-6	yds. 546,030 Rs. 6,10,569	136,338 1,03,390	lb. 221 Rs. 1,150	— —	7,15,109
1906-7	yds. 575,245 Rs. 6,02,336	86,740 82,526	lb. 172 Rs. 1,150	11 60	6,86,072

The exports have thus in recent years been steadily decreasing, the value of the piece goods exported having shrunk during the years 1900-1 to 1906-7 to less than one-half. The total value of all manufactured goods has similarly shrunk from 12½ to a little under 7 lakhs. If, however, the comparison be carried farther back, the decline is manifested as even still more serious. For the five years ending 1895-6 the exports of manufactured silks of all kinds were valued at 19½ lakhs of rupees. The finer silk fabrics made in India are nearly entirely used up in the country. In 1904-5 the value of the Bengal exports of all kinds amounted to Rs. 5,76,390, or almost four-fifths of the total. The share of Bombay, which means chiefly imported silk for the home market, was Rs. 1,34,749, while the balance went from Madras and Burma. Turning to the chief markets, we find that in 1906-7 the United Kingdom imported Indian goods to the value of Rs. 3,44,850; France, Rs. 80,135; Arabia, Rs. 62,581; North Africa, Rs. 23,229; Straits Settlements, Rs. 55,348; Turkey-in-Asia, Rs. 33,715; and Australia, Rs. 12,013.

Decreasing.

Shares of Bengal
and Bombay.

Imports.—These show a remarkable expansion. In 1876-7 they were valued at 58½ lakhs, five years later at 135 lakhs, and a decade still later (1890-1) 140 lakhs of rupees. Since 1900 the figures have been as follows:—1900-1, Rs. 1,66,58,108; 1901-2, Rs. 1,48,47,009; 1902-3, Rs. 1,63,23,232; 1903-4, Rs. 1,83,34,720; 1904-5, Rs. 2,11,81,502 (the highest figure yet attained); 1905-6, Rs. 1,90,15,100; and in 1906-7, Rs. 1,82,50,465. The largest quantities in 1906-7 came from Japan, Rs. 74,01,060; China, Rs. 33,97,558; France, Rs. 20,19,303; Italy, Rs. 19,84,466; the Straits Settlements, Rs. 1,02,307; the United Kingdom, Rs. 13,95,680; and Austria-Hungary, Rs. 3,06,661; while the chief

Imports.
Expanding.

gg-plant
Into Bombay
and Burma.

importing centre is Bombay, which takes almost three-fourths, the balance going chiefly to Burma. Reviewing the trade returns for 1904-5, Robertson (*Rev. Trade of Ind.*, 1904-5, 17) says: "Piece goods of pure silk are chiefly of Chinese and Japanese make, the latter predominating, and jointly (including re-exports from the Straits Settlements) they amounted to 16·3 million yards, valued at 102 lakhs, out of a total of 18·9 million yards, valued at 124½ lakhs. The value of the silk goods mixed with other materials, 43·8 lakhs, is 30 per cent. greater than in 1903-4. There is also an advance of 25·8 per cent. in 'other sorts,' of which the value rose by 51·7 per cent. to 42·9 lakhs. This includes warp and yarn of Italian silk imported into Bombay for hand-weaving." The expansion of the imports in mixed silk and other textiles and in thread, warp and yarn, is therefore a highly significant feature of the modern silk traffic that gives a useful hint as to the demands of the hand-loom workers.

Hand-weaving.

Re-exports.

Re-exports.—Have been increasing in recent years, and in 1904-5 were not far behind the exports in value. The figures for the period discussed were as follows:—1900-1, Rs. 5,33,749; 1901-2, Rs. 6,72,841; 1902-3, Rs. 7,33,519; 1903-4, Rs. 6,98,160; 1904-5, Rs. 6,01,942; 1905-6, Rs. 6,47,797; and 1906-7, Rs. 6,77,683. Bombay exports practically the whole amount, and the chief markets for these re-exported goods appear to be Natal, Arabia, British East Africa, Cape Colony and Persia.

From Bombay.

Trans-
frontier.

Trans-frontier Trade.—Turning from the foreign to the Trans-frontier land trade, the returns may similarly be indicated under exports and imports of raw and of manufactured silks. **OF RAW.**—The exports during recent years have been as follows:—1904-5, 189 cwt., valued at Rs. 85,233; 1905-6, 190 cwt., valued at Rs. 93,586; 1906-7, 94 cwt., valued at Rs. 51,175. The chief markets are the South Shan States, Bhutan and North-East Afghanistan. The imports during the same period have been:—1904-5, 2,960 cwt., valued at Rs. 19,98,484; 1905-6, 4,121 cwt., valued at Rs. 29,37,592; 1906-7, 4,165 cwt., valued at Rs. 30,88,935. **From Kashmir.** Kashmir and Western China supply practically the whole amount. **OF MANUFACTURES.**—The following are the returns of re-exported silk goods:—1904-5, 667 cwt., valued at Rs. 8,97,079; 1905-6, 710 cwt., valued at Rs. 8,11,581; 1906-7, 969 cwt., valued at Rs. 9,36,406. The chief markets are the South Shan States, North Siam, North Shan States, South Siam and Tibet. The imports for the same period were:—1904-5, 196 cwt., valued at Rs. 4,72,833; 1905-6, 445 cwt., valued at Rs. 7,33,319; 1906-7, 250 cwt., valued at Rs. 5,01,206. The largest quantities come from North and South Siam and the South Shan States.

De Candolle considers it is a native of Asia (not America), and other botanists have viewed it as Arabian. There are many very distinct forms or races distinguished by

EARLY SUMMER VEGETABLE

OLANU
LONG NA
Brinjal

the shape and colour of the fruit, egg-shaped to an elongated pear or even cylindrical, while in colour it ranges from white through yellow to red and even dark purple. None are eaten in the fresh state but are cooked as vegetables.

Cultivation.—The seeds are sown at the beginning of the rains and the plants put out at the distance of a foot and a half apart. They come into season in August or September and bear till the end of the cold weather, certain varieties yielding till June and in Madras right through summer to October. In the suburbs of Calcutta, Bombay and Madras, in other words, in the vicinity of large towns, the *brinjal* is cultivated as a field crop. Full accounts of cultivation have recently been given by Mukerji and Roy for Bengal, and by Mollison for Bombay. The latter states that the varieties with purple fruits grow into much-branched shrubs about 3 feet high. The small-fruited forms are not so tall. The field varieties, he further adds, have prickles. The crop is grown chiefly in Gujarat, especially in the *goradu* or *besar* garden lands of Kaira and Baroda. The crop is obtained from transplanted seedlings. The seed-bed is carefully prepared in May, and the young plants are ready for transplantation in six weeks or two months. The field into which they are transferred is prepared as for chillies, *i.e.* ploughed two or three times and then harrowed till a fine tilth is obtained. Before the first ploughing, a dressing is given of not less than 20 tons old farm-yard manure per acre. The seedlings are planted two together in rows, $2\frac{1}{2}$ to $3\frac{1}{2}$ feet apart in both directions. When well established they should be earthed up, before which a top-dressing of 500 lb. of nitre or 1,000 lb. of castor-cake placed round the plants will be found very beneficial. Beds for irrigation and watering are arranged as in the case of chillies (*Capsicum*). Mollison gives a table showing the yield, cost of cultivation, and value of outturn per acre under fairly high-class cultivation. The table shows that nitre as a top-dressing has a remarkable effect on the crop. With a manure of dried fish and nitre, at the rate of 1,451 lb. fish and 433 lb. nitre per acre, the outturn was found to be 16,322 lb., cost of cultivation Rs. 138-6, and value of outturn Rs. 325-5 per acre.

In Bengal, according to Mukerji, the seed is sown at the end of March or early in May. The field to which the seedlings are transferred is prepared in December or January and should be ready for planting in May. The plants begin to bear in August. A variety, known as *kuli begun*, is sown in September and October; the seedlings are transplanted in October or November and the plants bear from February to June. He estimates the cost of cultivation at Rs. 60-8 per acre, and with an outturn of 150 maunds per acre, worth Rs. 90, the net profit would amount to about Rs. 30 per acre. Roy puts this matter more pointedly. There are two principal varieties, he says—(1) the winter and (2) the spring. The finest *brinjals* are known as *elokeshi* and *mukta keshi*. When grown as a spring crop *brinjal* follows *aus* paddy or jute. But where the rainfall is heavy it is grown in the *rabi* season.

Uses.—*Brinjals* are much eaten by the Natives whenever procurable, and by the Europeans during the early summer months, when other vegetables are not available. The Natives use them (a) in curries; (b) roasted in hot ashes and mashed with salt, onions, chillies, and lime-juice or mustard-oil; (c) cut into slices and fried in oil; and (d) pickled while young and tender with mustard-oil, chillies, salt, etc. By Europeans they

Potato.

. **tuberosum**, *Linn.* The Potato, *alú*, *bilati álu*, *batata*, *wallarai*, *kilangu*, *utalay gudda*, etc.

With reference to the indigenous habitat of the potato, *De Candolle* (l.c. 45-53) states that the only locality in which a species is found really wild, that could be accepted as representing the cultivated plant, is Chili, but that it is very doubtful whether its natural home extends to Peru and New Granada. According to *Baker* (*Journ. Linn. Soc.*, xx., 489), however, undoubted forms of *S. tuberosum* have been found wild in Lima and in New Granada also, but the plant is everywhere one which occurs at a comparatively high altitude and in a dry climate, and is met with nowhere in the near neighbourhood of the coast. It is proved beyond doubt that at the time of the discovery of America the cultivation of the potato was practised with every appearance of ancient usage in the temperate regions extending from Chili to New Granada (*Asa Gray, Scient. Papers*, 1889, i., 317). In Europe it was introduced at some period between 1580 and 1585, first into Spain, thence to Portugal, Italy, France, Belgium and Germany. It had reached Ireland in 1585 or 1586 (*Rozé, Hist. de la Pomme de Terre*, Paris, 1898). The first mention of it in connection with India appears in *Terry's* account of the banquet at Ajmir given by *Asaph Chan* to *Sir Thomas Roe* in 1615 (*Voyage E. Ind.*, 197). *Fryer* (1675, *New Acc. E. Ind. and Pers.* (ed. 1698), 104, 179) describes the gardens of *Surat* and the *Karnátak* as containing among other vegetables *brinjals* and potatoes. It would thus appear that within a remarkably short interval, after the discovery of the potato in America, it had been conveyed to India and was apparently at once taken up by the better-class *Muhammadans* as a desirable addition to the ordinary articles of diet.

Ancient
Cultivation.

Introduction
into Europe.

Into India.

Cultiva-
tion.

CULTIVATION.—To-day, it may be said to be cultivated more or less in all parts of India. The methods pursued will, therefore, be now briefly indicated under provincial headings:—

engal.

Bengal.—The chief potato-growing districts are *Hughli*, *Bardwan*, *Rangpur*, *Jalpaiguri* and *Darjeeling*. Full accounts have recently been given by *Mukerji* and *Roy*, as also in the publications of the *Bengal Agricultural Department*. Various kinds of the tuber are grown, of which the *Patna*, *Naini Tal*, and *Cherrapunji* are best known and most highly valued. A loose soil such as sandy loam is preferred. The crop requires moisture, but water must not be allowed to settle about the tubers. In rotation it may follow *áus* paddy or *jute*, but is often grown year after year without an intervening crop, especially in the vicinity of large markets, the fertility being preserved by high manuring. Previous to planting the land is prepared by numerous ploughings and is thoroughly pulverised. Manure, preferably cow-dung at the rate of 240 maunds per acre, or castor-cake

Ploughing.
Manuring.

at the rate of 20 maunds per acre, should be spread on the ground after the first few ploughings and thoroughly mixed with the soil. The field is then divided into sections by water-channels and laid out in ridges and furrows. Sets consisting of entire tubers or portions with two or three "eyes" are planted along the ridges, 9 to 12 inches apart in a single or double row. Experiments at the Sibpur Farm showed that the average outturn per acre from double rows was about 9,500 lb., and from single rows about 7,300 lb. Planting the sets should not ordinarily take place in the plains before October. Between planting and harvesting, the crop should be watered if necessary, but not in excess, the earth stirred and weeded and heaped up several times round the base of the growing plants. Harvest takes place from 15th January to 15th March. Mukerji estimates the cost of cultivation at Rs. 170 per acre and the outturn at 150 maunds valued at Rs. 225, giving a net profit of about Rs. 50.

[Cf. Ghosha, *Potato and Its Cult.*, Journ. Agri.-Hort. Soc. Ind., 1871, ii., pt. ii., 296-309; Basu, *Agri. Lohardaga*, 1890, pt. i., 74-5; Banerji, *Agri. Cuttack*, 1893, 108-10; *Admin. Rept. Bengal*, 1901-2, 16-7; Mukerji, *Handbook Ind. Agri.*, 1901, 336-43; Roy, *Crops of Beng.*, 1906, 113-9; *Ann. Repts. Dept. Land Rec. and Agri.*; *Agri. Dept. Beng. Bull.*, 1906, No. 8; *Exper. Farm Repts. Bardwan*, 1906-7, 33-40.]

Assa .—Potatoes are extensively grown on the higher slopes chiefly in the Khasia hills, and in lower land which has been well drained. In the *Gazetteer of Assam* (1906, x., 73-4), which deals with the Khasia, Jaintia, Garo and Lushai hills, it is stated that the crop was first introduced in 1830 by Mr. David Scott and in 1881-2 the export of potatoes from the province reached 127,000 maunds. Five years later, however, the tuber was attacked by disease and in 1887-8 the export fell to 42,000 maunds, and in 1899-1900 had decreased to 5,000 maunds. A change then came, due to the introduction in 1897 of the Naini Tal potato, and in 1903-4 the exports reached 51,000 maunds. Two crops are raised: "The first is sown in January and February, and is gathered in June and July; the second is sown in July and August and is harvested in November and December." [Cf. *Ind. Gard.*, Sept. 29, 1898, 429-30; *Repts. Dept. Land Rec. and Agri.*; *Agri. Dept. Assam Bull.*, 1904, No. 10, 5-7.]

United Provinces of Agra and Oudh.—The potato is said to flourish well in the hills at Naini Tal, Almora, Paori Lohygar, and beyond Mussourie and also in the plains. Duthie and Fuller (*Field and Garden Crops*., pt. iii., 15-6) state that cultivation is conducted on the European method, and differs in no material respect from that described above for Bengal. Two hundred maunds is stated to be no extraordinary outturn, but the cultivation is very expensive. "The eyes are planted in November and the potatoes are ready for digging up in February. They are sold in the bazar at the rate of 12 annas to one rupee and four annas per maund." On the authority of the late Mr. Gollan, it is also stated that "the best time to sow the acclimatised varieties is from the middle of September to the middle of October, and that the hill kinds and those imported from Europe must be sown later. Water is freely given during growth, but the quantity is reduced when the leaves begin to turn yellow. If the soil is naturally rich, manure is not essential, but in the plains manure is always given."

In recent years three varieties have been experimented with at the Cawnpore Farm, viz. the Madras white, country red, and hill variety. In the report for 1903-4 it is stated that the average outturn for six years

Yield.	of Madras and hill varieties amounted to 13,527 lb. and 8,546 lb. respectively, while the average for five years for country red amounted to 13,119 lb. [<i>Cf. Nevill, Dist. Gaz.</i> , 1904, iv., 46; 1904, xxxiv., 56, 63, 150, etc.; <i>Cawnpore Exper. Farm Repts.</i> (several years).]
Bombay.	Bombay. —The potato is grown to a small extent on garden lands in all parts of the Presidency. The chief cultivation, however, is in the Poona district, which, according to Mollison, claims 75 per cent. of the total area. The following is the method of cultivation which he says is there pursued :—The soil is mixed black, and the field usually fallowed during the rains. The land is ploughed two or three times between June and September and farm-yard manure, 15 to 20 tons per acre, applied before the third ploughing. The crop is planted in October. Tubers of medium size are selected for sets, and 900 lb. to 1,100 lb. of potatoes furnish sets sufficient to plant an acre. The tubers are each cut into three or four pieces and are planted 7 to 8 inches apart, in furrows 9 to 10 inches distant. The crop must be weeded and irrigation given every eight days. In March the haulms begin to wither and turn brown, and water is now withheld for a fortnight or three weeks. When gathering the crop, the potatoes are exposed by ploughing, first along the rows, then across. According to Mollison, an average crop in Poona tested by himself gave an outturn of 10,230 lb. per acre, worth Rs. 201. The cost of cultivation, estimated for the Surat district, is stated to be Rs. 130–8 per acre, and an average outturn of about 12,000 lb. to be worth Rs. 200 (at wholesale rate of 60 lb. per rupee). [<i>Cf. Crop Exper. Repts.; Repts. Dept. Land Rec. and Agri.; Exper. Farm Repts. Poona; Mollison, Textbook Ind. Agri.</i> , 1901, iii., 200–6.]

Uses.	Uses. —It is much to be regretted that no sort of statistical information can be furnished regarding the extent of cultivation of potatoes nor the magnitude of the traffic in these tubers throughout India. As already mentioned, within access of the great markets of the plains it is customary to find large plots of suitable land thrown under the crop, during the season of the year that may be suitable. And on the hills the cultivation is even more extensive, such as on the Khasia and Garo hills, and the Himalaya at Darjeeling, Nepal, Garhwal, Kumaon, Simla, Kangra, Kullu and Kashmir. So also on the tableland and lower hills of the central tracts of India, such as the Nilgiri hills, Bangalore, etc., extensive potato cultivation exists, the produce being largely exported to the plains.
Production on the Hills.	
Hindus.	As an article of food, potatoes are now valued by all classes, especially the Hindus on days when forbidden the use of grain. At first potatoes
Muhammadans.	were eaten by the Muhammadans and Europeans only, but for some years past they have got into universal usage, and it is now no uncommon circumstance to find cooked potatoes offered for sale at refreshment stalls,
Cooked Potatoes Sold.	in various cold preparations, to be eaten along with so-called sweetmeats that form the midday meal of the city communities. The dried small tubers are also a common adulterant for the more expensive <i>salép</i> . Potatoes are also fairly extensively employed both in the manufacture of starch and in the distillation of alcohol. Ligon (<i>Hist. Barbados</i> , 1657, 31) speaks of the beverage called <i>mobbie</i> being made from potatoes. The knowledge of their possible employment in distillation is thus by no means a recent discovery.
Starch. Alcohol.	
Prices.	The following are the returns of the wholesale prices per maund (82 lb.) of potatoes in Calcutta during January of the years 1900–6 :—1900, Rs. 2;

1901, Rs. 2-8; 1902, Rs. 1-10; 1903, Rs. 1-4; 1904, Rs. 1-4; 1905, Rs. 2-3-9; 1906, Rs. 3-4-3.

O GHUM, Pers.; GRAMINEÆ. A genus of grasses which embraces several useful species, as, for example, the important millet *juár*—a cereal, which, after rice, is perhaps the most valuable single article of food in India. The present brief review of information may therefore commence with a botanical statement of *Sorghum halepense*, the plant from which the cultivated *S. vulgare* (*juár*) is believed to have originated. [Cf. Watt, *Agri. Ledg.*, 1905, No. 6.]

S. halepense, Pers.; *Andropogon halepensis*, Brot.; Prain, *Beng. Plants*, 1903, ii., 1204; *A. Sorghum*, subsp. *halepensis*, Hackel, in *DC.*, *Monog. Phaner.*, 1889, vi., 501; *A. (subgen. Sorghum) halepensis*, Fl. Br. Ind., vii., 182; Duthie, *Fodd. Grass. N. Ind.*, 1888, 40-4; Lisboa, *Bomb. Grass.*, 1896, 74. The Johnson Grass, Cuba Grass, etc., *barú*, *braham*, *kálá-mucha*, *galla-jari*, *padda-jallagadi*, *gadi-janu*, *kartál*, *bikhonda*, etc. A tall perennial grass, common throughout India and Burma on cultivated and uncultivated lands. There are two forms met with in India, which were treated by Roxburgh as separate species but exhibited thus in the *Flora of British India*:—

a. **Var. genulina** (*Andropogon miliaceus*, Roxb.). Lisboa mentions *narvas* and *bhonda* as vernacular names for this plant.

β. **Var. e usa** (*A. laxus*, Roxb. (non Linn.)). According to Roxburgh, this is the plant denoted by the names *kálá-mucha*, *gadi-janu*. He says it grows in hedges, on banks of watercourses and on land lately cultivated.

It is considered a good fodder grass both for grazing and for hay, but is held to have frequently poisonous after-effects, especially if eaten when too young or when stunted by drought. In many parts of India it is believed to be injurious till after the rains. The name *bikhonda*, given to *S. halepense* in certain mountainous countries, may be intended to denote its evil reputation. The grain is often collected and eaten, though the plant seems nowhere to be specially cultivated. Hamilton, for example, speaks of a kind of bread being made from it in Rajmahal, and Tod (*Rajasthan*, ii., 170) mentions the seed being collected, mixed with *báira* and eaten by the poorer classes in Bikanir. [Cf. Sly, *Exotic Drought Resisting Plants*, in *Agri. Journ. Ind.*, 1907, ii., pt. ii., 168.]

. **vul re**, Pers.; *Holcus Sorghum*, Linn., *Sp. Pl.*, 1753, 1047; *Andropogon Sorghum*, Brot.; *Holcus Sorghum*, Roxb., *Fl. Ind.*, i., 269; *A. Sorghum*, Prain, *Beng. Plants*, 1204, ii.; *A. Sorghum*, subsp. *sativus*, Hackel, in *DC.*, *Monog. Phaner.*, vi., 505; *Fl. Br. Ind.*, vii., 183. The Indian or Great Millet, Guinea Corn, Turkish Millet, etc., *juár*, (*jovar*), *jondhala*, *kurbi*, *chari* (stalks), *phag*, *kangra*, *shálu*, *sundia*, *cholam*, *talla*, *jonna*, *yengara*, *pyoung*, etc. A tall, handsome grass, cultivated throughout India since very remote times.

Though botanists are agreed that the *juár* is derived from *S. halepense* it has been dispersed by cultivation to latitudes considerably to the north and south of its indigenous habitat. In most countries it is cultivated between latitudes 45° N. and 35° S.—the area of cotton. In India and

Distribution.

Africa it is of greatest value in the upland tracts between latitudes 15° and 30°. In warmer, moister regions, as in Bengal, in large portions of Madras, in Lower Burma, and in Ceylon it hardly ranks as an important cereal, since in these regions the grain ripens but indifferently.

Names,

History.—According to Crooke (*Rural and Agri. Gloss.*, 1888, 139; also his edition of *Hobson-Jobson*, 1903, 468), the word *juár* has been derived from the Sanskrit *yava-parkāra* or *akāra*, which means “of the nature of barley.” Dutt (*Mat. Med. Hind.*, 324) mentions *yávanāla* and *rakta-khurna* as its special Sanskrit names. From *yávanāla* it would become *javanāla*, *javanāra*, and finally *juár*. The Arabic *dūra* (or, as it is variously written, *dhurra*, *dhaura*, *douro*, etc.) readily becomes *zūra* and has been Sanskritised as *zurna*, and is thus but a variant of *juár*. It would seem probable that the earliest mention of the name *dūra* (or *дорah*) occurs (9th century A.D.) in Avicenna's reference to the people of Zanzibar living very largely on the grain of that name. The Javanese name for it is *djagomutri*. The *cholam* is probably also the *tsjolam* of the Malabar (Rheede, *Hort. Mal.*, xii., 113, t. 60). It certainly is the *battari* of the Malays (Rumphius, *Herb. Amb.*, v., 194, t. 75).

Sorgho.

The origin of the name *sorghum* or *Sorgho* might be expected to throw much light on the history of the crop. Rees (*Cyclopædia*, 1819), followed by Paxton, Johnson, and most botanical lexicographers, says it is an Oriental word and comes from the Indian *sorghi*. This doubtless is a mistake, since no such name for it exists in any Indian language. Körnicke and Werner (*Handbuch Getreidebaues*, 1885, i., 294-315) seem to think that it came direct from the Arabic *dorah*. The initial letter, on its passing westward, became softened into “th” and ultimately into “s.” Sadebeck (*Kulturgew. der Deut. Kolon.*, 1899, 48-52) and many other authors speak of it as the *sirch* of the Southern Tyrol.

First mentioned.

John Arduin in his notes on Pliny (ii., 105, n. 23), published 1723, observes that Scalinger (*Exercit.*, 1557, 292, 869) is responsible for the statement that his countrymen, the Italians, called it *surgum*. Schweinfurth (*Heart of Africa*, 1873, i., 246) says that Petrus de Crescentius, about the year 1290 A.D., is the first author who definitely alludes to *sorgo*. However, in the editions of the *Agricultura*, dated 1471, 1519, and 1553, *melica* (*milica*) and in Italian versions *sagina* occur, but not *sorgo*. Porta (*Villæ*, etc., 1592, 865), accepting Pliny's statement that this millet came from India to Italy in the time of Nero, observes that it was called by the Italians *sagina*, *melica*, or *surga*. He then gives a derivation of the last name from “*surgo*, to rise,” in allusion to its towering above all other crops. It would seem that the word *Sorghum*, as it now exists, originated in Europe, and is strictly speaking the name for the warm temperate grain-yielding races of the plant, the forms that correspond with the *rabi juár* of India presently to be described.

Rabi Juár.

European Travellers.

Few, if any, of the European travellers in India, whose writings, as a rule, are so fruitful of historic evidence, make any reference to this grain. Yet we can have little doubt that it was extensively cultivated in India during at least the period of the explorations indicated. In the *Ain-i-Akbari*—the Administration Report of the Emperor Akbar for the year 1590—its price is quoted in a list of autumn grains, and in a further passage (Gladwin, transl., ii., 62) it is remarked that—“*Jewary* and *Bajera* are the grains chiefly cultivated in the Subah of Guzerat.” So again, speaking of Khandesh (Jarrett, transl., ii., 223), we read—“*Jowari* is chiefly cultivated, of which, in some places, there are three crops in a year, and its stalk is so delicate and pleasant to the taste that it is regarded in the light of a fruit.” It is, however, comparatively little grown on the Malabar coast even to the present day, and was hardly likely, therefore, to have been seen by the traders and travellers who for the most part visited the coast towns. Koernicke, who maintains with De Candolle, that as a cultivated plant it originated in Africa, not India, observes that it probably reached Asia by sea and not by land routes, as was often the case. But if that were so, we might expect to find it most extensively cultivated near the coast, whereas when we first learn definitely about it in India, it is the staple food of the people who occupy the interior and drier tablelands, not the warm, moist regions near the sea. It is, in fact, met with approximately in regions where its presumed wild stock *Sorghum halepense* is most plentiful.

African, not Indian.

Indian For

We may, therefore, conclude that in all probability the Sanskrit people first learned of this grain in India, but gave themselves very little concern regarding it. Everything, however, points to its having been cultivated in the peninsula

VARIETIES AND RACES

FOOD SUPPLY.

Varieties and Races.—Speaking in a very general sense, there are two great crops of *judr*. Of these one is the *kharif*, which ripens in autumn. The majority of the *kharif* forms would fall under the botanical varieties *bicolor*, *cernuus*, and *vulgaris* proper. They have usually compact heads, the grains are more or less rounded, and the floral envelopes almost completely glabrous. The second crop is the *rabí*, or that which ripens in spring. It seems likely that most of the races placed in this position would be found to fall under the varieties *hians*, *Roxburghii* and *saccharatus*, and to approximate nearer to *S. halepense* than do those of the *kharif* series. They have lax feathery panicles with the grains elongated and the floral envelopes often more or less hairy. As a rule the best kinds are creamy white (the extremity only being darker coloured) and of a pearly lustre. It is customary for the grain to be slightly flattened near the apex, a peculiarity often much increased until in some forms it becomes almost hooked or even indented. The curved grains are generally the most highly prized, for the purpose of being parched. The glumes or envelopes are usually darker than the grains themselves, and may be awned or awnless. In some forms the envelopes (chaff) are coloured and the grain-husk (or seed-coat) white; in others the seed-coat also is uniformly or parti-coloured. Lastly, the floral envelopes may firmly embrace and almost adhere to the seed, while in other conditions the attachment may be so slight that (as in certain barleys) the grain may deserve the description of being naked.

Mollison (*Textbook Ind. Agri.*, iii., 10-11) says: "The most noticeable differences between varieties are that *kharif*, i.e. rain crops or early varieties are much more numerous than *rabí* or late varieties. Early or late varieties do best if sown at their approximate seasons. A *rabí* variety may or may not thrive if sown as a rain crop. None of the rain crop varieties are likely to succeed if sown in the *rabí* season." In the experiments conducted at the farms in the Bombay Presidency it was established that forms of *judr* procured from *goradu* (light) soils—for example, those of Kaira and Baroda—could not be cultivated on the black cotton soils of the Deccan. Thus there would seem no doubt centuries of selection and special cultivation have directly adapted this plant into the numerous recognisable races that exist in India.

Area and Yield.—From the *Agricultural Statistics*, 1900-1 to 1905-6, this crop is shown as occupying in British India approximately 22 million acres. To these figures have to be added $2\frac{1}{2}$ million acres for the Native States, making the total of some 24 million acres for all India and Burma. The chief provinces in order of importance are Bombay, Madras, Berar, the United Provinces, Central Provinces and Panjáb. An almost identical

Soils:
Influences.

Area and Yield.

distribution exists in the Native States : *juár* becomes important on land not inundated. Out of the total mentioned, Gwalior takes usually close on half, that is, a little over one million acres. This is followed by Mysore with about half a million acres, by Kotah State with 350,000, and by Tonk and Jaipur, having about the same acreage between them.

Yield. It has been estimated that a yield of 6 maunds (or, say, 500 lb.) an acre might be a safe though probably a low average for the crop. To be rather under than over the mark, therefore, this would come to an annual production of, say, 5 million tons of grain. Mukerji (*Handbook Ind. Agri.*, 1901, 254) says of *juár*, "It yields a nourishing grain about the same quantity per acre as wheat or rice (900 lbs.) and ten times as much in fuel and fodder as ordinary cereal crops." Mollison (*l.c.* 8-9), speaking of the Deccan *kharif juár*, remarks : "An average crop in the Deccan will vary, according to the quality of soil, from 500 to 900 lb. per acre of *jowár* and 100 to 200 lb. subordinate pulses with 350 to 450 bundles of *kadbi*" (fodder). Referring to the Gujarat *rábí juár*, Mollison continues : "An acre produces 800 lb. to 1,000 lb. grain and 300 to 400 bundles of *kadbi*; each bundle weighs 4 to 6 lb. The fodder is usually of excellent quality, because the crop stands fairly thick upon the ground and the stalks are neither very tall nor very coarse. A *rábí* crop in other black soil districts yields generally in a fair season 550 to 700 lb. per acre." In the *Report of the Experimental Farm at Surat for 1903*, the yield is given as 1,213 lb. grain, by-products 3,974 lb., the value of the outturn Rs. 34-3-1, and the cost of cultivation Rs. 30-14-0 an acre. These returns, as also Mollison's figures, may be accepted as in accord with the numerous crop experiments that have been performed in Bombay.

Grain and Fodder.

Value of Crop.

Diseases.

Smut.

Striga.

Watching.

Climatic Disturbances.

Poisonous if Diseased.

Early Maturity.

DISEASES AND PESTS.—The Sorghum crop is exposed to four chief adverse circumstances :—(1) fungal blights; (2) parasitic flowering plants; (3) insects and other animal pests; and (4) climatic disturbances. Massee (*Textbook Plant Diseases*, 216) gives particulars regarding smut. Much advantage might be anticipated from the systematic washing of the seed in hot water (at a temperature of 135° to 150° F.), or in sulphate of copper ($\frac{1}{2}$ per cent. solution), before being sown. By this process the crop would be protected against smut and bunt. Of the parasitic flowering plants found on this crop the most curious is the small *Striga* (known in the vernacular as *tavli* or *taluk*), which sometimes effects frightful havoc. One or two parasitic insects do much damage (such as the sugar-borer and an aphid), but birds and squirrels are by far the most destructive. To safeguard the crop, the owner watches it from sunrise to sunset for some twenty days before the harvest. For this purpose he and his assistants sit on elevated platforms, placed at intervals all over the field, and make discordant noises by beating on old tins, or cast by slings small stones or hardened pellets of mud at the flocks of birds which every now and again settle on the field. The climatic disturbances may be briefly stated as want of rain at the proper season, excessive humidity and cloudy weather, or unnaturally high temperatures. In a further paragraph, while dealing with the production of this plant as a source of fodder, reference will be made to the evil reputation of the stems for becoming poisonous. This peculiarity is not constant, though it often occurs in an epidemic form such as to justify belief that the germ concerned in the production of the poisonous property is dependent upon accidental climatic or disease conditions. The plant stunted because of deficiency of rain is always a dangerous fodder for cattle. A study of the races of the plant, more critical than hitherto attempted, might therefore be looked to as likely to result in the discovery of forms better suited to certain tracts of country than those at present grown. On this aspect Mollison's pertinent observation may be given here :—"Some varieties mature much more quickly than others. It is important to know which varieties reach maturity earliest; because after a period of scarcity or famine, varieties which produce grain and fodder in the least time would be most in demand."

Cultivation

It may be added that since the above was published in *The Agricultural Ledger*, Maxwell-Lefroy has given many useful particulars regarding the Moth-borers found in the Sugar-cane, Maize and Sorghum (*Agri. Journ. Ind.*, i., pt. ii., 97-113; also *Mem. Dept. Agri. Ind.*, 1907, i., No. 2). No one has as yet, however, written a complete account of the diseases and pests of this crop for the whole of India, but Barber (*Dept. Land Rec. and Agri. Mad. Bull.*, 1904, ii., No. 49) gives a review of the available information so far as the Southern Presidency is concerned. He there deals with the subjects of Smut, Shredding of the Leaves, Wet Weather Mould, Reddening of the Leaves, Rust, Mites, Red-spot Disease, Insect and Other Animal Pests, Borers, Plant Lice, Plant Bugs, Weevils in the stored grain, *Striga*, etc. An interesting account of the fungal disease caused by *sclerospora graminicola* (also described by Barber, *l.c.* 278) is given by Butler (*Mem. Dept. Agri. Ind.*, 1907, ii., No. 1, 13-4). [*Cf. Watt, Agri. Ledg.*, 1895, No. 20, 285; and Barclay, 375, 378.]

Rotation.—The advantage of sowing mixed with the bushy pulse *tur* (*Cajanus indicus*) turns very largely on the protection afforded from severe droughts and destructive winds. The action of leguminous crops on the soil is, however, valuable, and a mixed crop may on that account serve part of the purpose of a rotation. The rotations most frequently seen are cotton, and *juár* with *tur* mixed; cotton, *juár*, *tíl*; cotton, *juár*, *san* hemp (the last often ploughed in as a green manure); or cotton, *juár*, fallow. *Juár* is supposed to participate in the manure and cultivation bestowed on the cotton. Farm experiments have proved the three rotations distinctly preferable. The special value of the use of *tíl* (*sésamum*) lies in the fact that being a late crop it allows of the land being thoroughly ploughed every third year. Besides the plants mentioned many others are used, but as these may now and again be referred to in the observations below, nothing further need be added to the scheme of rotation just indicated.

CULTIVATION.—**Bombay and Sind.**—There are usually $5\frac{1}{2}$ to 8 million acres under this crop in Bombay, and about half to three-quarters of a million in Sind. But this may be more fully exemplified thus:—In 1905-6 the total area in Bombay was 6,570,339 acres, and the chief districts within the area were—Bijápúr, 1,209,066 acres; Sholapur, 1,313,422 acres; Ahmadnagar, 662,918 acres; Poona, 681,413 acres; Sátara, 600,097 acres; Belgaum, 583,184 acres; Dharwar, 567,091 acres; Khandesh, 432,638 acres; Násik, 74,541 acres; Ahmadabad, 249,881 acres, etc. In the *Season and Crop Report*, published by the Department of Agriculture, the area in 1906-7 is stated to have been 5,643,000 acres in Bombay, and 630,000 acres in Sind. Mention has already been made of the large number of recognisable forms of the plant in this Presidency. Discussing the merits of those grown at the Surat Experimental Farm, the Superintendent, in his Report for 1902-3, speaks of 23 having been found superior grain varieties, and then adds that 269 forms have been under experiment.

Stress may be laid on the relatively greater importance of the *rabí juár* crop in Bombay than in the other provinces of India. It follows accordingly that a larger percentage of the Bombay forms of the plant might be looked for as belonging to the group with open feathery panicles and saccharine stems. Many valuable reports and special publications have appeared, such as those in connection with the Experimental Farms and the Crop Experiments. Mollison tells us that *juár* is the staple grain crop where black and mixed black soils predominate, provided the rainfall is moderate and well distributed. Where rainfall is excessive, it gives place to rice, and on sandy loams and shallow soils to *bajra*. Mollison then refers his account of this cereal to the sections shown in the following abstract:—

(a) The Kharif Juár of the Deccan.—The land should be ready for sowing by the end of June: later sowings are not so satisfactory. The amount of seed to be used depends to a large extent on the kind cultivated. Large-headed forms require more space. But the ordinary rate of seed is 6 to 8 lb. an acre along with

Rotation.

Bombay.

Areas.

Districts.

Races.

Rabí Crop.

Deccan.
Season.

1½ to 2½ subordinate pulses. The seeds are mixed and drill sown, the rows being 14 inches apart. In successful cultivation the crop is hand-weeded as well as hoed once or twice. The crop will come into flower in August and September and ripen in October and November.

Gujarat.
Kharif.

(b) The Kharif Juár of Gujarat.—Usually alternates on black soil with cotton: after removal of the latter, the land is repeatedly harrowed and scarified in April and May, but no ploughing is, as a rule, given since juár likes a firm seed-bed. In June or July the seed is drilled in rows 20 inches apart. When the crop stands 9 inches high, it is again hoed and the plough passed between the rows of seedlings. The principal crop is ready five months after sowing.

Rabi.

(c) The Rabi Juár of Gujarat.—In Broach this form of juár is called *shialu*. It is drill-sown in September or October, after one ploughing and several harrowings of the soil. The seed is sown at the rate of 7 to 8 lb. an acre. The rows are 20 inches apart, and the seedlings appear in the furrows. The crop is twice intercultured with the bullock hoe. "As the ears begin to fill, the stalks are tied up to each other so that they may not be lodged." This is only necessary in a good year, with a heavy crop. Harvest takes place in February to March, or five to six months after sowing.

Madras.
Areas.

Districts.

Madras.—In 1905-6 there were 4,740,841 acres under the crop. The areas in the chief districts in that year were as follows:—Bellary, 725,444 acres; Coimbatore, 704,593 acres; Karnul, 678,290 acres; Cuddapah, 414,359 acres; Anantapur, 304,499 acres; Guntur, 381,929 acres; Nellore, 356,589 acres; Madura, 297,693 acres, etc. According to the *Season and Crop Report*, the area in 1906-7 was 4,479,193 acres. Large portions of Madras, being rice-producing countries, have only small areas under juár (or *cholam*, as it is called in South India).

Mysore.

Mysore has usually a little over half a million acres, chiefly in Mysore and Chitaldrug districts. Of Mysore, the published averages of yield have shown from 453 to 800 lb.

*Early and
Late Crops.*

An exhaustive account of *Sorghum* in Madras has been written by C. Benson, Deputy Director of Agriculture, and C. K. Subba Rao, Sub-Assistant Director of Agriculture (*Dept. Agri. Mad. Bull.*, 1906, No. 55, 58 *et seq.*). These authors state that the outturn varies within wide limits. "The *punasa* or early crops of Sorghum give a larger outturn of comparatively poor fodder, but less grain, than the *hingári* or late crop. The outturn of unirrigated Sorghum varies from 200 to 600 lb. per acre. Under irrigation, the yield on the average is double that amount. The outturn of dry straw from an unirrigated crop on fairly good land is two full cartloads per acre" (*l.c.* 117-8).

*Climatic
Characteristics.*

"The chief characteristic of the climate of the principal areas in the Madras Presidency where sorghum is an important field crop, is the lightness of the rainfall. The only exception is that part of Nellore and Guntur adjoining, where the annual rainfall is 30-40 inches. Elsewhere the usual fall is less than 25 inches and in some places as little as 20 only." There are two main seasons for sowing, an early at the beginning and a late towards the end of the south-west monsoon. The early-sown crops are raised chiefly on the lighter soils. "On the mixed and more loamy soils, the middle season varieties are usually found, and the late-sown crops on the heavy soils." The crop is regarded as an exhausting one, and its growth, year after year, on the same land, is considered bad practice, but is not uncommon. It is stated that "speaking generally, on loamy or sandy soils sorghum, following castor or horsegram, is looked upon as the best rotation, while the ryots will not grow sorghum if they can avoid it after a crop of Italian millet or *varagu*." Again, "The commonest practice is to sow sorghum mixed with other crops, which vary according to the nature of the soil, the season and the local customs."

Soils.

Rotation.

*Mixed
Cultivation.*

"In the Deccan districts green gram and other puls, gingelly and *gogu* (*Hibiscus cannabinus*) are mixed in small and irregular quantities with the sorghum seed for an early crop and sown through the drill, while red gram, *amumu* (*Dolichos Lablab*), cow gram (*Vigna Catjang*), and castors are sown in lines amongst the crop."

AN IMPORTANT GRAIN

GHU
VULGA
Cultivation

"In the southern districts, somewhat similar mixtures are made and the whole is sown broadcast, while it is a common practice to sow the red gram in lines at intervals of about six feet apart in the furrow made with a plough" (l.c. 94).

The methods of preparatory tillage, of sowing, and treatment during growth are fully described, but cannot be gone into here.

Berar and Hyderabad.—The area under the crop in 1905-6 was 2,660,144 acres in Berar. The average for the five years previously was approximately three million acres. Hyderabad furnishes no returns.

The following information is abstracted from an interesting account by S. Harcourt King (*Agri. Bull.*, 1900, No. 3). While written professedly for Amraoti, F. W. Francis comments that the account is applicable to all the Hyderabad Assigned Districts (Berar). *Juár* is undoubtedly the most important grain crop of the province—more than one-third of the total cultivated area being devoted to it. There are no less than 43 varieties, 12 of which come under the denomination *wani*, or forms which are baked in hot ashes and eaten green, when the grain is tender. Of the other forms, four groups are formed according to their value as sources of bread, viz:—(1) the yellow *juárs*—the bread made from these is considered best; (2) whitish *juárs*—the bread is hard and wanting in taste; (3) reddish *juárs*—bread is of the same colour as the grain; (4) dirty-coloured *juárs*—seldom utilised for bread, but in making *láhi* (parched grain). Unless the soil is very hard or full of weeds, *juár* lands are ploughed once in four or five years only, and then in April or May. Usually the soil is simply harrowed, generally three times. The crop is rotated with cotton, sesamum, gram, wheat, *lák* (*Lathyrus sativus*) and tobacco, and is generally grown as a mixed crop, along with certain pulses. Weeding is done three or four times at intervals of a fortnight. *Juár* is never specially watered in Berar apparently, nor is it customary to grow the crop on land systematically irrigated. This is the rule for the grain crop, but when required to make up deficiencies of fodder, thickly sown and irrigated crops are taken. *Juár* requires good rain in August and it comes into ear from three to four months after being sown, and ripens in five months (November to December). In a good season the yield would be 833 lb. to the acre, and, after making all allowances, an estimate of 600 lb. would be a fair average production.

In Hyderabad it is stated that there are two crops of *juár*: the one sown from the 6th June to the 17th July and reaped from the 22nd October to the 30th November. The second crop, known as white *juár*, is sown between the 25th September and the 3rd November and reaped between the 17th February and the 15th March.

United Provinces.—In 1905-6 the area in Agra was 2,095,995, and 353,161 acres in Oudh. In Agra the largest areas are:—Jhansi, 235,287 acres; Hamirpur, 169,346 acres; Cawnpore, 160,903 acres; Mattra, 122,021 acres; Aligarh, 106,150 acres; Balandshahr, 102,440 acres; Meerut, 102,334 acres; Agra, 95,002 acres; Farukhabad, 92,894 acres; Budaun, 85,283 acres; Etah, 78,822 acres; Mainpuri, 77,777 acres, etc. No district in Oudh, except Rai-Bareilly, has usually over 55,000 acres under the crop. The *Season and Crop Report* states the area in 1906-7 to have been 2,371,154 acres in Agra, 335,839 in Oudh.

Duthie and Fuller (*Field and Garden Crops*, i., 25) mention three well-marked varieties:—(1) the double-seeded form with two grains within a single husk; (2) a dwarf kind, grown at Allahabad; (3) the variety known *chácha* in Cawnpore, which the grain is completely covered by the husk. In the report of the Cawnpore Experimental Farm for 1901-2, mention is made of 90 varieties

ORGHUM

VULGA

Central Provinces

Yield. being under cultivation. The yield is given at 10 maunds grain for irrigated land and 8 maunds for unirrigated. In the reports of crop experiments, returns ranging from 440 to 820 lb. have been ascertained.

C. Prov. *Central Provinces.*—The area in 1905–6 was 1,860,714 acres. The largest areas in that year were :—Nagpur, 423,121 acres ; Wardha, 282,536 acres ; Chánda, 223,130 acres ; Nimar, 202,926 acres ; Chhindwára, 188,982 acres ; Bhandára, 87,637 acres, etc.

Chief Food. *Juár* constitutes the chief food of the working class, wheat and rice being alike but little used by them. The white variety is the most highly prized. In certain districts, such as the Upper Godavari and the neighbourhood of Sironcha in Chanda district, a *rabi* as well as a *kharif* crop is obtained. Repeated mention is made (in reports on this plant) of a cold-season form known as *ringni*. Some writers even speak of this as a hot-weather plant that has recently been successfully grown as a cold-season crop. It is commonly produced in the rice-country of Ramtek and Umrer.

Forms Grown. Sir J. B. Fuller published in 1894 *A Note on the Outturn of Land under the Chief Crops in the Central Provinces*, in which he gives most useful particulars regarding *juár*. He points out that the loss through its being grown as a mixed crop with a pulse (mostly *tur*, p. 196) is very little indeed, so that the pulse is a clear gain. The yield per acre averages from 450 to 950 lb. ; 500 lb. has been accepted as the average standard. He further remarks that Nagpur, which has the largest district area, is also the chief importing province and that it draws on Berar. This is due very possibly to the place of *juár* being taken by linseed and cotton. In the *Settlement Report for Seoni* (1900, 17), it is observed that a few years ago *juár* was of very little importance in that district, but since the last three years it has been greatly extended, and outrun the area under wheat. In recent *Annual Reports* by the Director of Land Records and Agriculture, interesting particulars will be found of valuable experiments made with a view to improve the quality of the *juár* and the cotton grown, as also the methods of cultivation pursued in the districts of Bilaspur and Raipur. Trained ploughmen had been sent from the Government farm, furnished with superior seed and improved ploughs, to prepare and sow certain fields. The result would appear to have been so satisfactory that many indents were subsequently made by the cultivators for a supply of improved seed. Demonstration farms have since been organised where local men, specially trained at the Government farm, would continue to exemplify the advantages of the improvements recommended.

Cold-season. Sir J. B. Fuller published in 1894 *A Note on the Outturn of Land under the Chief Crops in the Central Provinces*, in which he gives most useful particulars regarding *juár*. He points out that the loss through its being grown as a mixed crop with a pulse (mostly *tur*, p. 196) is very little indeed, so that the pulse is a clear gain. The yield per acre averages from 450 to 950 lb. ; 500 lb. has been accepted as the average standard. He further remarks that Nagpur, which has the largest district area, is also the chief importing province and that it draws on Berar. This is due very possibly to the place of *juár* being taken by linseed and cotton. In the *Settlement Report for Seoni* (1900, 17), it is observed that a few years ago *juár* was of very little importance in that district, but since the last three years it has been greatly extended, and outrun the area under wheat. In recent *Annual Reports* by the Director of Land Records and Agriculture, interesting particulars will be found of valuable experiments made with a view to improve the quality of the *juár* and the cotton grown, as also the methods of cultivation pursued in the districts of Bilaspur and Raipur. Trained ploughmen had been sent from the Government farm, furnished with superior seed and improved ploughs, to prepare and sow certain fields. The result would appear to have been so satisfactory that many indents were subsequently made by the cultivators for a supply of improved seed. Demonstration farms have since been organised where local men, specially trained at the Government farm, would continue to exemplify the advantages of the improvements recommended.

Mixed Cultivation. Sir J. B. Fuller published in 1894 *A Note on the Outturn of Land under the Chief Crops in the Central Provinces*, in which he gives most useful particulars regarding *juár*. He points out that the loss through its being grown as a mixed crop with a pulse (mostly *tur*, p. 196) is very little indeed, so that the pulse is a clear gain. The yield per acre averages from 450 to 950 lb. ; 500 lb. has been accepted as the average standard. He further remarks that Nagpur, which has the largest district area, is also the chief importing province and that it draws on Berar. This is due very possibly to the place of *juár* being taken by linseed and cotton. In the *Settlement Report for Seoni* (1900, 17), it is observed that a few years ago *juár* was of very little importance in that district, but since the last three years it has been greatly extended, and outrun the area under wheat. In recent *Annual Reports* by the Director of Land Records and Agriculture, interesting particulars will be found of valuable experiments made with a view to improve the quality of the *juár* and the cotton grown, as also the methods of cultivation pursued in the districts of Bilaspur and Raipur. The areas manifest extreme fluctuations, the unirrigated *juár* being chiefly grown in Dera Ghazi Khan, Gujrat, Rawalpindi.

Races. There are said to be many races of the grain, and in most districts it would appear as if special fodder (*chari*) forms had only recently been systematically cultivated. The *Gazetteers* afford useful particulars, but it would seem that since the date of Baden-Powell's *Panjáb Products* (1868, 236) no publication has discussed the *juár* cultivation of the province as a whole.

en al. *engal and Assa* .—Although grown by the hill tribes to a limited extent, *juár* cannot be regarded as an important crop in these provinces,

nor in fact in any rice-producing country. The area under it is in Bengal usually about 150,000 acres. In 1906-7, according to the *Season and Crop Report*, the area was 143,700 acres, chiefly in the Bhagalpur and Patna Divisions. Eastern Bengal usually has about 5,000 acres, and Assam a purely nominal acreage devoted to the crop. In the *Annual Report of the Bardwan Experimental Farm* (1901-2) particulars are given of experiments with black-seeded and also red-seeded forms as fodder crops. Further experiments with other forms are alluded to by the Director of Agriculture in his *Annual Report* (1902-3).

Fodder.

Bur a.—The crop is important in Upper Burma, where in 1905-6 it occupied 856,437 acres, but in Lower Burma, the rice country, it is very unimportant. The chief districts of Upper Burma are Pakokkú, 203,345 acres; Myingyan, 190,635 acres; Lower Chindwin, 133,977 acres; Magwe, 93,851 acres; Meiktila, 92,130 acres; Sagaing, 90,594 acres, etc. Results of crop experiments have shown the yield to vary from 328 to 875 lb. an acre.

Districts.

Results.

Recent *Settlement Reports* have furnished some useful particulars regarding this crop. Speaking of Myingyan, we read that "the seed was said to have been introduced" after the famine of 1856-7. Blanford reported having seen it in Pagan in 1862. There are two forms recognised—(1) *sanpyaung*, grown for human food: it has a round white seed with yellow husk; and (2) *kun-pyaung*, grown for fodder, but not exclusively so: it has both red and brown grains. Both crops are sown in July and August and gathered in December and January. The stalks, which often run up to 18 feet in height, are given to cattle after being chopped up and mixed with water.

Introduction.

Forms.

Seasons.

Speaking of the Meiktila district, we read in the *Settlement Report* that *juár* is one of the chief upland crops. It is in greater request as an article of food in the western than in the eastern portions of the district, owing primarily to the fact that the scope of the cultivation of paddy is somewhat limited in the former. There are three kinds:—(1) *kun-pyaung*, has a reddish-brown seed, is not deprived of its husk on being threshed, and gives the highest return; (2) *sanpyaung*, gives the lowest return in proportion to the seed sown, since in the process of threshing and winnowing it is entirely cleared from the husk, so that nothing but the little pearly yellowish seeds remain. It has a better appearance than the *kun-pyaung*, and yields after being milled 11 as compared with 8 from the *kun-pyaung*; (3) *pyaung-net-si*—this is not very extensively cultivated. It has a jet black husk and forms (like *kauk-hmyin* rice) a glutinous mass when cooked, and is used for cakes and other sweet confections. The *juár* is sown in August and September and reaped in January and February, being a six months' crop. It grows well in paddy fields provided water is not allowed to stand in them, and when scarcity of water prevails it often takes the place of paddy. The ground is prepared by harrowing the surface at least ten times and the seed is then broadcasted.

Upland Crop.

Glutinous Form.

FODDER SUPPLY.

Ripe and Green Ste s.—The *juár* crop is not alone of value as a food for man. Its stems constitute the chief cattle fodder (*chari*) of a large portion of India. The first signs of famine directly induced by the loss of the *juár* crop are the starvation and death of the cattle. It thus follows that in India it is the ripe stems and leaves (the straw, it might be called) which become the Indian *juár* fodder. Here and there special races of the plant are grown as a supply of green fodder. Mollison, speaking of the Bombay Presidency, mentions some six indigenous forms of fodder *juár*:—(1) *sundhia*—perhaps the best fodder variety; (2) *dudhia*—this is met with on the light-coloured soils of Kaira and Baroda; (3) *nilva*—this is the best Deccan (Poona) fodder for the monsoons; (4) *utávli* is another Deccan form with loose upright heads of grain; (5) *hundi* and (6) *kálbondi* are recommended for cultivation as

Fodder.

Special For .

Green Fodder.

Poisonous Property

The Most
Suitable Form.

irrigated crops and should be sown any time between November and February. Mollison then observes (*l.c.* 16): "No other crops can compare with the Sorghums in yielding a heavy weight of green fodder of good quality. Succulent fodder of this class is specially valuable in the hot weather for all farm animals, and *hundi* and *kálbondi* are the most suitable varieties yet found for the purpose."

Dried Fodder.

storage.

Ensilage.—Mukerji (*Handbook Ind. Agri.*, 255) says that sorghum fodder may be sown "in May, and sowing should continue through June and July, that there may be a succession of fodder crops of first, second, and third cuttings from July to March or April, a portion of which can be dried and preserved for use from April to June. The dried stalks should be stacked and thatched." Mollison describes the manner of preserving sorghum fodder followed in the Southern Maráthá country. "The bundles are built into neat oblong heaps in the field. Each heap is built with a slope from the ground to the ridge, and when complete is protected along the sides, ends and top with big lumps of black soil, which are built or packed closely together. These heaps when complete look like large boundary marks. Cattle can freely graze over the stubble, but can get no access to the stored fodder." Voelcker has expressed himself as opposed to the introduction into India of the European methods of siloing sorghum fodder, and the reports published by the Experimental Farms of India are as a rule unfavourable.

Poisonous
Property.

Poisonous Property.—It has been already observed that the name *bikhonda* given to the wild *S. halepense* may be intended to denote the well-known poisonous property which that grass sometimes manifests. It may perhaps be accepted as a further proof of the descent of at least the fodder-yielding cultivated forms of *Sorghum vulgare* from that wild plant, when it is added that under certain circumstances the cultivated sorghums also become poisonous. In this connection attention may be invited to the fact that the Hemp Drugs Commission in their *Report* (1893, i., 156), and more recently the Excise Commissioner of the Central Provinces, have made known a new use of the root of the *juár* plant that seems to have escaped the observation of previous writers (see p. 758). It would appear that it is employed to increase the potency of Indian hemp (*bhang* and *ganja*) as well as of country liquor, but is viewed as too powerful to be used by itself. A poison residing in the root is certainly remarkable and worthy of the most careful and searching future inquiry, and it may be added that it is said to occur also in the roots of rice, but so far as *juár* is concerned, is reported as found only in the cold-weather or *ringni* (Central Provinces) and *shidlu* (Bombay) varieties.

Root used with
Indian Hemp.

Poison
Simultaneous.

Young Plant.

Prussic Acid.

The occurrence of this poisonous property is, moreover, often simultaneous over a large tract of country, appearing and disappearing within certain fixed limits of time and locality. It would thus seem that the effect of climatic disturbances in modifying the quantity and quality of the crop has not received the degree of consideration which it demands. Pe e (*Agri. Ledg.*, 1896, No. 24, 225) has recorded the death of a large number of cattle at the Sirsa fair, due to their having eaten *juár* stems. The young plant has frequently been found to be poisonous to cattle in Egypt, the West Indies, United States and elsewhere. Dunstan and Henry have examined young sorghum plants from Egypt and India and have shown that these when ground up in contact with water yield prussic acid, and that the prussic acid originates from the interaction of a crystalline glucoside *dhuririn* and the unorganised ferment *emulsin*, both of which occur in the plants and are brought into contact in the manner just indicated. In Egypt the amount of *dhuririn*, and consequently the quantity of prussic acid obtainable, is at a maximum when the plants are about 12 inch

SORGHUM SUGAR AND SPIRIT

ORG UM
VULGA
Trade

high, after which it gradually disappears as the plant matures (*Phil. Trans.*, 1902, excix. a, 399). Apart from the variation in the amount of prussic acid obtainable, which accompanies the ripening of the plants, variation appears also to be caused by climatic and other influences since sorghum plants at the same stage of growth yield different quantities of prussic acid in different countries. Dunstan and Henry's observations have been confirmed by Leather in India (*Agri. Journ. Ind.*, 1906, i., pt. iii., 220-5), Brunswick in Queensland, Avery in the United States and other investigators, so that there can be no doubt that the toxicity occasionally exhibited by green sorghum is due to this property of producing prussic acid. Stephenson has recorded that a sample of Indian sorghum examined by him contained considerable quantities of potassium nitrate, and suggested that this might be the cause of the poisonous character of the plant; but apart from the fact that potassium nitrate is not poisonous, the facts recorded above leave no doubt that Stephenson's assumption is erroneous. His observation is, however, of special interest since many of the plants which contain cyanogenetic glucosides of the dhurrin type have been found to contain also notable quantities of potassium nitrate, and Trent has shown that in such plants there is reason to believe that the potassium nitrate is utilised as a source of nitrogen for the synthesis of the characteristic glucosides they contain. [*Cf. T. A. Williams, Sorghum as a Forage Crop, in U.S. Farmer's Bull.*, 1899, No. 50; Lyon and Hitchcock, *Forage Crops, U.S. Bureau of Plant Indust. Bull.*, 1904, No. 59.]

Variation with Growth.
With Climatic Influences.

Potassium Nitrate.

Source of Nitrogen.

SUGAR SORGHUM OR IMPHEE.—In Bikanir and Ajmir a form of sugar-yielding sorghum, designated the *Alipura*, has been known and cultivated from time immemorial and used in the preparation of the sugar-candy for which these towns are famed. This statement was discussed some years ago in *The Indian Agriculturist*, but seems to have been contradicted and then forgotten. In 1890 an official inquiry in the Panjáb resulted in the report that while in Ferozpur, Sialkot, and elsewhere sweet sorghums were known, the saccharine property was lost after a few years' cultivation in other districts to which these plants had been experimentally conveyed. Of the exotic forms, the amber and the collier seem to have attracted most attention. But according to the *Poona Farm Report* (1895, 9) there was little to choose between them either in percentage of sugar or value as fodder crops. The weight of molasses per acre was found to be—collier, 1,174 lb., and amber, 1,072 lb. [*Cf. Wigley, Note on Sorgho, Rev. Dept. Govt. Ind.*, 1877; *Prod. of Sugar from Sorghum, U.S. Dept. Agri. Bull.*, 1890, No. 26; Wiley, *Exper. with Sorghum, Bull.*, 1890, No. 29; 1891, No. 34; 1892, No. 37; *U.S. Yearbook Agri. Dept.*, 1897, 80; 1899, 242-3; *Exper. Stat. Record*, 1899, x., 345; 1900, xi., 141, 319, 883; 1901, xii., 236, 547, 942; 1902, xiii., 42-3, 242; 1903, xiv., 757; *U.S. Farmer's Bull.*, 1899, Nos. 90, 92; *Agri. Gaz.*, 1891, 134; 1894, 579; *Journ. Agri. S. Australia*, 1902, v., 876; *Rev. des Cult. Colon.*, 1902, xi., 51; *Journ. Soc. Chem. Indust.*, 1902, xxi., 628.]

Sugar.

Sweet Property Lost.

Chief Forms.

Spirit.—Many writers allude to the fact that the Africans manufacture a sort of beer from the grain of sorghum. In 1884 Minchin Brothers of Aska, Ganjam, reported that the juice of sorghum was most valuable to distillers. The spirit prepared is said to have tasted much like rum, but after being opened was liable to throw down a gelatinous-looking substance. Nothing further has been heard on the subject in India, and of the United States of America it has generally been said that changes in the fiscal laws would be necessary before it could be utilised.

Spirit

TRADE IN JUÁR.

It is exceedingly difficult to furnish any very definite statement regarding the traffic in the products derived from *Sorghum vulgare* in India, for the simple reason that as a rule the official statistics treat of the two millets—juár and bájra—conjointly. It would, however, seem fairly safe to assume that two-thirds of the quantities recorded are in reality juár, the balance being bájra. The estimate of total production given above for juár alone comes to 100 million cwt. of grain. The exports of juár and bájra together during the years 1901-2 to 1905-7 have averaged about 1½ million cwt.; assuming that two-thirds are juár, we learn that the total exports do not exceed 1 per cent. of the production. Juár is, therefore, grown primarily to meet the food necessities of the people

Trade.

Total Production.

Local Consumption.

and not (as in the case of rice in Burma) as a rent-paying article of export.

Internal Traffic.

The quantities of *juár* and *bájra* conjointly shown as carried by rail and river average about 4 to 5 million cwt. in normal years. In the year 1899-1900 the traffic became 11 million cwt.; in 1900-1 it stood at 9 million cwt.; in 1901-2 at 8 million cwt.; in 1902-3 it fell to its normal condition of $4\frac{1}{2}$ million cwt.; in 1903-4 it was close on $4\frac{1}{2}$ million cwt.; in 1904-5 it again rose to $8\frac{1}{2}$ million cwt.; in 1905-6, to $9\frac{1}{2}$ million cwt.; and in 1906-7 was $7\frac{1}{2}$ million cwt. During the years of scarcity and famine (1900-3), Bombay Presidency imported in 1899-1900, 4 million cwt.; in 1900-1, 5 million cwt.; in 1901-2, 3 million cwt.; in 1902-3, $1\frac{1}{2}$ million cwt.; while the town of Bombay itself took in addition 2, $\frac{3}{4}$, $\frac{1}{2}$, and 1 million cwt. These supplementary supplies were drawn from Madras, the United Provinces, Sind, etc. In 1903-4 the imports into Bombay Presidency fell to less than a quarter of a million cwt., while those into Bombay town stood at 2 million cwt.; in 1904-5 they were about 2 million and $2\frac{1}{2}$ million cwt. respectively; in 1905-6, $2\frac{1}{2}$ and about $1\frac{3}{4}$ million cwt; lastly, in 1906-7 they were $1\frac{1}{2}$ million and $\frac{3}{4}$ million cwt. The traffic with the other provinces and chief towns is hardly worthy of special comment.

Supplementary Supplies.

Coastwise Traffic.

Turning now to the records of the coastwise traffic, we obtain a similar indication of the interdependence of the provinces of India for this all-important foodstuff, especially during abnormal years or local climatic disturbances. The returns of imports show that Bombay draws on Sind, Madras and Burma, and exports to Kathiawar and Kach.

Prices.

Prices.—The official returns (*Prices and Wages in India*) afford some useful particulars. The mean average price of *juár* for all India during the years 1871-5 is taken as 100, the standard of comparison of relative prices in the districts and provinces of India, also of accidental disturbances. During the quinquennial period 1896-1900 (which includes a term of scarcity and famine) the mean average for the whole of India was 153·6, and in 1903, when the effect of the famine had been effaced, it stood at 109·23; but if three provinces be removed from consideration, namely Berar, the Panjáb and Sind, the mean average for the whole of the rest of India becomes 100·6. In the three provinces named (except some districts of the Panjáb), *juár* never seems to have been procurable at the price expressed by the standard of 100. As exhibiting the actual average prices of this millet, it may be here stated that, expressed in seers (= 2 lb.) and decimals of seers obtainable for one rupee (or 1s. 4d.), the returns of Burma in 1906 show 20·07; Bengal, 12·51; Agra, 14·36; Oudh, 14·05; Rajputana, 14·53; Central India, 15·26; Panjáb and North-West Frontier, 16·24; Sind and Baluchistan, 16·4; Bombay, 13·52; Central Provinces, 15·45; Berar, 18·3; Nizam's Territory, 13·8; Madras, 14·24; Mysore, 14·6.

Influence of Famine.

Seers to the Rupee.

Equalisation of Prices.

It may thus be said that approximately in districts of chief production, the number of seers obtained per rupee is higher than in localities where the millet is not very largely grown. A similar series of quotations for a number of years would show that railway extension has equalised the price in relation to production. The most significant feature of the internal trade returns is perhaps the circumstance that Bengal practically takes no part in the traffic. Millets are, in fact, very little consumed in Bengal. Another feature may be said to be that the great producing areas export to tracts of country inhabited by simple agricultural communities or to

INDIAN DISTILLING

regions where modern civilisation with its concomitant luxury has not penetrated to any material extent.

PI IT , d I di Distillin.—Many of the intoxicating liquors sold in India perhaps hardly deserve the name of SPIRITS. They embrace both fermented and distilled liquors, and can be conveniently grouped as Foreign and Country. To a small extent WINES and BRANDY are produced in Kashmir, but the bulk of the vintage beverages are imported. BEERS and ALES are brewed in India under the most improved European methods (see *alt Liquors*, pp. 757-62), but they are also largely imported ; SPIRITS are distilled both after the most primitive Native and the most advanced European methods, so that country spirits (*arak*), as well as rum, brandy and whisky can be had all over India—both of foreign and Indian brands.

D.E.P.,
v., 332-4 ;
vi., pt. iii.,
331-7.
Spirits.

Dutt (*Mat. Med. Hind.*, 272) observes that the fermented and distilled liquors that cause intoxication are by Indian classic authors called *madya* or *madirā* (Sansk.). He then enumerates some 20 forms of spirits which appear to have been recognised as different, such as those distilled from the grape, the date, sugar-cane, rice, barley, wheat and from the flowers of the *mahua*. Ray (*Hindu Method of Manuf. Spirit, Journ. As. Soc. Beng.*, 1906, ii., No. 4, 129-42) gives a highly instructive and interesting sketch of the Indian knowledge in spirits.

Different Kinds.

Arak is perhaps the most generally accepted vernacular name for spirits. Moodeen Sheriff (*Pharmacop. Ind.*, suppl., 56, 275) gives, among others, the following synonyms :—*sharāb*, Hind. ; *mad*, *surap*, Beng. ; *dāru*, Guz., Duk. ; *shārāyam*, Tam. ; *sārāyi*, Tel. and Kan. ; *aye*, Burm. Regarding the name *arak*, or, as it is often rendered by Europeans, *arrack* or *rack*, the observations in *Hobson-Jobson* (ed. Crooke, 36) may be exhibited briefly :—“ This word is the Arabic *arak*, properly ‘ perspiration,’ and then, first the exudation or sap drawn from the date-palm (*arak al-tamar*) ; secondly, any strong drink, ‘ distilled spirit,’ ‘ essence,’ etc. But it has spread to very remote corners of Asia.” Thus *ariki*, *arki*, Mongolia and Manchuria ; *rāki*, Turkish, etc. The word *pachwai* (see p. 757) denotes a beverage (beer) made from malted grain, but when distilled this becomes *phatika* or *madira*. In Sanskrit, three kinds are distinguished according to the grain used—*surā* (rice), *kohala* (barley), and *madhulika* (wheat). So also fermented sweet liquors, such as palm-juice (*tari*) or honey and water or cane-juice, would correspond closely with ale, and when

Sweet Liquids.

distilled become the spirit more especially designated *arak*. In Sanskrit the spirits or grades of *arak* from sweet liquors would be *sidhu* (from sugar-cane = rum), *gaudi* or *gouri* (from treacle), *kharjura* (from date-juice), and *maddhika* (from grapes = brandy). It would thus appear that the English word alcohol came from the Sanskrit through the Arabic *al-kohl*, namely from *kohala*, which is derived from *ku* (the earth) and *hala* (poison).

History.

istory.—The knowledge possessed by the Natives of India in spirits of various kinds is very widespread, and dates back to the classic periods. Rajendralála Mitra has shown (*Journ. As. Soc. Beng.*, 1873, xlii., pt. i., 1, 58) that spirits and other intoxicating drinks have been extensively used in India at all times and by all classes. Rice spirit was both drunk and used in sacrifices during the earliest Vedic times: the leading characters of the *Mahābhārata* were addicted to strong drinks; in the *Ramayana* the use of spirits is mentioned with approbation: in the time of Kalidása, drinking was common not only among men but even with women of high rank: the *Puranas* abound in descriptions of spirits and of drinking: and lastly the *Tantras* afford abundant proof of the attachment on the part of a large section of the Hindus to over-indulge in spirituous drinks. Manu condemns the use of *surá*; *kohala* and *jagala* are described in *Susruta*, a medical treatise of the 5th century. In Buddhist works, on the other hand, the use of spirits is stringently prohibited, and in Muhammadan writings, more especially the *Koran*, it is similarly proscribed, so that with the orthodox followers of the Prophet the use of strong drinks is discountenanced. But during the time of the Mughals in India, intemperance was the rule rather than the exception. The Emperor Baber (*Memoirs*, 258, 354) takes pains to describe, with minute detail, his drinking parties, and his subsequent renouncement of the use of wine. The *Ain-i-Akbari* gives full particulars of an intoxicating liquor made from sugar-cane, and the still employed in its production is that often seen in use to-day in the rural parts of India. The author of the *Ain* also records the fact that excessive spirit-drinking prevailed among the grandees at the Court of Akbar. [*Cf. D.E.P.*, vi., pt. iii., 331; also Sir George Birdwood's account of the strong drinks of India (*E.I.C. First Letter Book*, intro. and n., xxii.).]

European Influence.

Coming down to the commencement of European influence in India, Barbosa speaks of the "*hurrasa*" of Surat in 1516. Linschoten, in the 16th century, deplored the fact that the Portuguese soldiers were learning from the Natives of India the pernicious practice of drinking spirits in place of the wine imported from their own country. So also Pyrard (*Voy. E. Ind.* (ed. Hakl. Soc.), i., 358; ii., 73, 383) and Tavernier (*Travels* (ed. Ball), 1676, i., 243) mention a spirit distilled from palm wine which was largely drunk by the people of India at certain feasts. The latter also gives details of the method of its preparation. Thevenot (*Travels in Levant, Indostan, etc.*, 1687, pt. iii., 16), speaking of Surat, says that spirits were made of *jagre* and *babul* bark, also of *tary*. Thus the Natives of India certainly did not learn from Europeans the art of distilling spirits nor the habit of alcoholic indulgence. But there would seem little doubt that the special use of PUNCH originated with the Europeans resident in India. That word is accepted as derived from the Persian *panj* and the Hindustani *panch*, and means five. It thus denotes the ingredients of a special concoction in favour with the Europeans, viz. *arak*, sugar, lime-juice, spice and water. It would thus appear that the Europeans were not prepared to consume the Native *arak* undiluted and invented the above concoction much as the Greeks prepared their *pentaploa* (wine, honey, cheese, flour and oil). There is no evidence that the Natives ever used the special beverage indicated nor employed the word *panch* in the sense implied. Thus Mandelslo (1638) calls the Indian special mixture *palepunzen*. Hedges (1658) speaks of having often remembered the Company in a bowl of the clearest *punch*, while Fryer (1675) actually gives *paunch* the etymology of denoting the five ingredients of the special beverage.

Use of Babul Bark.

Punch.

Legislation.

Restriction and Legislation.—So far as can be learned, the system of supervision over the traffic in intoxicants, exercised by the Muhammadan rulers of India, was that of farming out the right of manufacture and sale to the highest bidder. The British Administration inherited that system, but soon began to introduce wholesale reforms. For some years past the policy pursued has been to tax the traffic to the utmost limit possible, short of originating illicit production. The aim has been to secure the maximum revenue from the minimum

Farmin
Manu-
facture.
Direct Taxation.

consumption. Thus out of the uncontrolled farming sprang the direct control of the British system. The first step taken was the limitation of the number of shops in the area farmed. Hence came the outstill system, under which the right to manufacture and sell at a specified shop was granted. But by neither of these measures was any limitation fixed on the duty per gallon—hence it became the interest of the producer to extend his transactions by lowering the price and thus to encourage consumption. This led to the Central Distillery system, in which the manufacture and storage are both under Government supervision, and a still-head duty had to be paid before issue from the cellars. But unfortunately it has not been found possible to enforce this system all over India.

Outstill
System.Central
Distillery.

Revenue.—The revenue derived from intoxicating beverages appears under "Customs" for imported liquors and under "Excise" for locally produced. The excise revenue on liquors would seem to have been steadily increasing for some years past, due, it is presumed, to two chief causes:—(a) the increasing prosperity of the lower classes and (b) the more complete supervision of the Excise Administration. This result may be exemplified thus—in 1860–1, the Excise revenue on liquors came to 91 lakhs of rupees (= £606,700); in 1870–1, to 156 lakhs; in 1880–1, to 212 lakhs; in 1890–1 to 349 lakhs; in 1900–1 to 427 lakhs; and in 1902–3 to 486 lakhs of rupees (= £3,240,000). Taking the last year, the following analysis exemplifies the relative importance of the chief kinds:—Revenue from country spirits, 325 lakhs of rupees; palm-juice, 111 lakhs; grain beer, 17 lakhs; country rum, etc., 12 lakhs; malt beer, 4 lakhs; and foreign liquors, 18 lakhs. Since then the revenue has continued to increase till in 1905–6 it reached over 625 lakhs or £4,166,767, made up as follows:—foreign liquors, £378,724; country spirits, £2,914,067; toddy, £873,976 (*Moral and Mat. Prog. Ind.*, 1905–6, 81). It is believed the total revenue for 1906–7 came to £6,510,000, but the increase shown by no means necessarily manifests expansion in consumption: to a much larger extent it denotes more complete control.

Revenue.
Excise.

Increase.

Incidence of Taxation.—"The average incidence of taxation per proof gallon of distillery spirit amounted in 1902–3 to Rs. 4–6–8, of which Rs. 3–4–6 was derived from still-head duty, and Rs. 1–2–2 from vend fees. Among the larger provinces, the average rate was highest in the Panjáb (Rs. 6–1–0) and in Burma (Rs. 6 plus vend fees), and lowest in the Central Provinces (Rs. 3–8–4). The average consumption per thousand of the population in distillery areas varied from 14 gallons in the Panjáb and 10 (roughly) in Burma, to 127 gallons in the Bombay Presidency proper" (*Imp. Gaz.* 1904, iv., 16). In the year 1900–1 the estimated consumption in gallons, per thousand of population, in distillery tracts, was as follows:—in Bengal, 18; in the United Provinces, 30; in the Panjáb, 11; in Madras, 22; in Bombay, 112; in Sind, 46; in Burma, 10; in Coorg, 162; in Hyderabad Assigned Districts, 65; and in Ajmir-Merwara, 59.

Taxation.

Materials Used.—Except in the Madras Presidency, country spirits (including the Panjáb country rum) is the main source of the revenue from intoxicating liquors. "It is usually prepared by distillation from the *mahua* flower, molasses and other forms of unrefined sugar, fermented palm-juice and rice—the last mainly employed in Bengal, Assam and Burma. Country spirit is prepared by Native methods in Bengal, Assam, the United Provinces, the Central Provinces, Sind, the Frontier Province and Baluchistan. The ingredients are generally fermented in pots and then distilled in rudely constructed stills. The system is very crude and the product apt to contain a considerable percentage of fusel oils. In Madras, Bombay, the Panjáb and Burma, manufacture of country spirit

Materials.

or of Indo-European spirit (local brands of rum, whisky, etc.) is, as a rule, carried on in highly organised private distilleries with European appliances" (*Imp. Gaz.*, l.c. 14).

The following may be given as a fairly complete enumeration of the materials used (or which may be used) in the distillation of various alcohols, chiefly consumed as intoxicants. The pages (when cited) denote positions in this work where details will be discovered:—

- Agave.—The Mexican *mescal* spirit (p. 35).
 Anacardium occidentale.—The Cashew-nut. A spirit is said to be distilled from this fruit in Goa (pp. 65-6).
 Pine-apple. Ananas sativa.—The Pine-apple (p. 69).
 Anthocephalus Cadamba.—Spirit distilled from the flowers.
 Arenga saccharifera.—The Sago-palm, employed in preparation of Batavian *arak* (p. 92).
 Mahua Spirit. Bassia latifolia.—The Mahua. flowers, perhaps after grain and sugar the most important alcohol-yielding material in India. The spirit distilled from these is called *madhvi* (p. 119). It is discussed by Baber (*Memoirs*, 1519, 325).
 Tari. Borassus flabellifer.—The Palmyra or Toddy Palm (p. 170).
 Caryota urens.—The Indian Sago-palm (pp. 286-7).
 Cocos nucifera.—The Coconut (p. 361).
 Coffea arabica.—Ripe pulp of coffee-berry (p. 366).
 Coix.—Beer (p. 396).
 Cymbopogon.—*Rusa* and other perfumes (pp. 450-63).
 Marua. Eleusine coracana.—The *marua* or *râgi* (pp. 519-21).
 Eugenia Jambolana.—The ripe fruits are distilled in Goa (p. 526); also largely used for vinegar (p. 1109).
 Beer and Whisky. ordeum vulgare.—Beer. See alt Liquors (pp. 643, 757). In Spiti a liquor is distilled from the grain called *chang* (p. 758).
 alt Liquors (pp. 757-62).
 elia Azadirachta.—The *nim*. A fermented liquor is obtained from the sap that is sometimes distilled (p. 780).
 orus alba.—The Mulberry fruit affords a beverage sometimes distilled in Kashmir (p. 785).
 Pachwai. Oryza sativa.—Rice. This is the chief grain used in the production of *pachwai*, and a spirit is often also distilled from specially prepared rice cakes (pp. 826, 840). The spirit from rice and barley cakes, J. C. Ray tells us, is called *paishiti*. The reader desirous of particulars regarding the method of distillation pursued in Bengal, should consult Ray's instructive paper (*l.c.* 130-42). The revenue from rice and millet beer amounted, in 1902-3, to about 6 lakhs in Bengal and 11 lakhs in Burma—elsewhere it is inconsiderable.
 Toddy Tari. Phoenix.—The sap of the Date-palm is largely employed in Bengal in the manufacture of crude sugar, and the fermented toddy is distilled or alcohol is made from the sugar (see p. 886). The sap of the date, palmyra and coconut palms (called *târi* in the north, and *toddy*, a corruption of *tari*, in the south) is used as a drink fresh or after fermentation. The total excise revenue derived from these sources in 1902-3 amounted to over one crore of rupees, of which about 72 per cent. was collected in Madras, 12 in Bombay, 10 in Bengal and 5 in Burma. Thevenot (*Travels in Levant, Indostan, etc.*, 1687, pt. iii., 17, 97) makes interesting mention of "tary" wine.
 Rum. Saccharum officinarum.—Sugar-cane. Rum is obtained chiefly by the distillation of the uncrystallised portion of the expressed juice (p. 956). Country brands of rum and the so-called brandies and whiskies are distilled from cane-juice, etc., and are coloured and flavoured as desired. Recently, however, some of the European breweries have started to distil whisky (proper) from barley, and this promises to be a profitable new industry. The cane-sugar liquors are produced at private distilleries situated in different part of the country. In the United Provinces and the Panjâb such liquors pay duty at the rate of Rs. 4 per proof gallon, in the Central Provinces at Rs. 5, and elsewhere at the Customs tariff rate of Rs. 6. The most important factory is the Rosa Distillery at Shah-jahânpur, in the United Provinces, which, in addition to supplying these provinces, exports considerable quantities to the Panjâb, the Central Provinces, Bengal and other parts of India (see p. 956).
 Sorghum.—A spirit is distilled from the grain (p. 1041).
 Vitis vinifera.—The Grape. Brandy is distilled in Kashmir (p. 1114).

Materials Used to Aid the For. ation of Alcohol or to Flavour or Strengthen the Beverages.

Acacia leucophloea.—Distillers' Bark (p. 15).

Cannabis sativa.—Indian Hemp (pp. 258-63).

"Cerevisiæ Fermentum."—Yeast. *D.E.P.*, ii, 257-60; see alt Liquors Yeast. (p. 758). The special preparation used in Bengal known by the name of *bakhar* (Ray, *l.c.* 130, 133) contains a diastase enzyme that possesses the power of converting starch into dextrine and maltose, but Ray adds the caking of the rice is as essential as the addition of *bakhar* but no caking takes place without *bakhar*.

Datura.—(p. 488).

umulus Lupulus.—See alt Liquors—Hops (p. 759).

Ligustrum Roxburghii.—The bark put into the toddy of *Caryota* in Madras.

Phyllanthus Emblica.—The fruit put into Native spirits (p. 887).

Sorghum vulgare.—Root added to increase the poisonous property of the liquor (see p. 1040).

Strychnos Nux-vomica.—The seeds added to beverages to make them intoxicating (p. 1052).

Terminalia bellerica and Chebula.—The fruits used to increase the potency of spirits (p. 1073).

Vateria indica, *Linn.* (see pp. 1105-6).

TRADE.—Production.—No sort of tabular statement can be furnished Trade.
that could make any pretensions to completeness in the exemplification of the production and consumption of intoxicating liquors in India. We know that there were 14 registered distilleries in all India during 1901 and that these employed 520 persons, each having at least 25 employees. But there were many smaller distilleries, each employing on an average fewer than the number of persons that justify registration. In 1902 and 1903 the registered distilleries were only 9, and in 1904 only 8, so that there would appear to have been some curtailment.

The quantities of spirits issued from the regularly constituted and registered distilleries is of course ascertainable, but not the amount of other intoxicating liquors issued by the smaller concerns, nor the production that is either authorised or not but which, nevertheless, takes place domestically. In 1903-4 the spirits issued from the distilleries came to 8,439,167 gallons; in 1904-5 to 8,744,302 gallons; and in 1905-6 to 9,288,013 gallons (*Rev. Trade Ind.*, 1905-6, 8). Registered Distilleries.

Foreign Imports.—To contrast with these figures of regular production of spirits, the following particulars regarding the imports from foreign countries of supply may be given :—The returns of foreign trade show that the imports of spirits into India have been steadily increasing. The following are the quantities of imported SPIRITS of all sorts during the six years 1901 to 1907 :—1901-2, 1,275,525 gallons, valued at Rs. 88,69,374; 1902-3, 1,380,953 gallons, valued at Rs. 95,18,881; 1903-4, 1,409,831 gallons, valued at Rs. 99,15,068; 1904-5, 1,444,207 gallons, valued at Rs. 1,00,59,285; 1905-6, 1,620,492 gallons, valued at Rs. 1,08,78,491; and in 1906-7, 1,489,361 gallons, valued at Rs. 98,69,497. Taking the figure for 1906-7, we find the total was made up thus :—BRANDY, 333,957 gallons, valued at Rs. 27,49,931; GIN, 68,575 gallons, valued at Rs. 2,63,877; LIQUEUR, 12,262 gallons, valued at Rs. 1,53,953; RUM, 66,579 gallons, valued at Rs. 1,09,245; WHISKY, 592,514 gallons, valued at Rs. 37,78,813; SPIRIT used in DRUGS, etc., 86,891 gallons, valued at Rs. 15,73,906; SPIRIT PERFUMED, 16,351 gallons, valued at Rs. 6,23,266; METHYLATED SPIRIT, 181,369 gallons, valued at Rs. 2,72,998; OTHER SORTS, 130,863 gallons, valued at Rs. 3,43,508. The shares of the chief countries in the total for 1906-7 were :—United Kingdom, 766,686 gallons; France, 256,472 gallons; Germany, 193,575 Imports.

Classification.Countries of Supply.

Importing
Provinces.

Arak
Imported.

gallons ; Straits Settlements, 56,218 gallons ; Ceylon, 56,665 gallons, etc. The quantities received by the different provinces were :—Bengal, 477,043 gallons ; Bombay, 426,343 gallons ; Burma, 250,879 gallons ; Madras, 199,815 gallons ; Sind, 133,832 gallons. A feature of the imports of some interest may be here mentioned, namely *arak* from Ceylon and the Straits, in direct competition with Indian production. It may also be added that the Indian Amendment Act of 1906, which came into operation on the 26th February, 1906, raised the rates of import duty on ordinary spirits from Rs. 6 to Rs. 7 per imperial gallon, and on liqueurs and perfumed spirits to a rate corresponding with that on ordinary spirits. The Amendment Act was thus intended to place imported spirits on a par with Native spirits in the matter of taxation.

Exports.

Exports.—The exports of spirits are small and unimportant, and during the five years under review have dwindled almost to nothing. The total exported in 1901–2 was 78,084 gallons, valued at Rs. 1,20,547 ; in 1902–3, 11,986 gallons, valued at Rs. 12,146 ; and in 1906–7 only 134 gallons, valued at Rs. 939. In addition, small quantities are also re-exported, amounting to 3,768 gallons, valued at Rs. 32,573 in 1906–7.

**Internal
Trade.**

Internal Trade.—Unfortunately no comparison can be made with the returns either of production or of imports, since the returns by rail and river are made in cwt. (not gallons), and moreover the spirits are classed along with wines (see p. 1119). But the total transactions in 1906–7 amounted to 189,045 cwt., and the distribution of that quantity can be exemplified. CALCUTTA exported 36,362 cwt. (Eastern Bengal and Assam 10,669 cwt., and Bengal 10,252 cwt. ; to United Provinces, 9,636 cwt.). BOMBAY PORT exported 41,528 cwt. (to Bombay Province 18,299 cwt. and to Central Provinces 5,611 cwt.). MADRAS PORTS exported 32,701 cwt. (to Madras Province 23,454 cwt. and to Mysore 7,584 cwt.). MADRAS PRESIDENCY exported 34,617 cwt. (to Madras Ports 16,323 cwt. and to Central Provinces 12,207 cwt.). KARACHI exported 20,467 cwt. (to the Panjáb, 12,582 cwt.). UNITED PROVINCES, 10,567 cwt. (to the Panjáb, 4,740 cwt.).

Coastwise.

A further conception of the internal traffic may be learned from a study of the transactions along the coast of India. The total exports of spirits coastwise in 1905–6 amounted to 1,875,882 gallons, valued at Rs. 58,57,808. Almost the whole of this quantity came from Bombay, viz. 1,744,683 gallons in 1905–6, and was consigned chiefly to British ports within the province.

QUILL.—Two bulbs are sold as Squills in Indian drug-shops, and more or less used indiscriminately, viz. *SCILLA* and *URGINEA*. The former is frequently regarded as the preferable quality, and is accordingly the one most largely traded in. The bulbs of *Scilla* are imbricated, those of *Urginea* are tunicated like the onion.

See also *ca. Baker* ; *Fl. Br. Ind.*, vi., 348 ; *Prain, Beng. Plants*, 1903, ii., 1074 ; *Cooke, Fl. Pres. Bomb.*, 1907, ii., 767–8 ; *LILIACEÆ*. The *suphadie-khus*, *bhui-kándá*, *shiru-nari-vengayam*, etc. A small bulbous herb, frequent in sandy places near the sea, in the Deccan peninsula from the Konkan and Nagpur southwards. This fact is mentioned by Fryer (*New Acc. E. Ind. and Pers.*, 1675, 178), who speaks of the squills or sea onions that grow near the sea on the Karnátak coast. The bulbs are used in India as a substitute for the true Squill, i.e. *Urginea Scilla*, which is imported into India from the Mediterranean, and *Urginea indica*, Kunth—the Indian Squill. It grows wild on the sandy shores near Bombay, but can also be cultivated on light sandy soil. Parker (*Rept. Proc. Cent. Indig. Drugs Comm.*, 1901, i., 39, 152–3) says, “The young small bulbs should

Bombay Squills.

be planted in ridges about 1 or 1½ inches below the surface just before the monsoon, much in the same way as onions are cultivated. The bulbs selected for medical use should be of medium size, neither too young nor too old. In the wild state, other bulbs are found growing with the *Scilla indica*, and have to be differentiated. Also bulbs collected on the hills are apt to be offered for sale as *Scilla indica*. The bulbs growing with the *Scilla indica* are oblong, not so spherical as the latter, and are yellowish in section. The hill bulbs are generally of larger size. The process of preparing the bulb, called *killingu*, consists in cutting it up into fragments and drying; this should be carried out in the cold season. The cutting should be done in the early morning so that the segments may be at once exposed to the sun for some hours, otherwise they blacken." [Cf. Rept. Proc. Cent. Indig. Drugs Comm., l.c. 152-3, 233-42, 289-91, etc.]

Medicine.

Substitutes.

Urginea indica, Kunth; (*Scilla indica*, Roxb.); *Fl. Br. Ind.*, vi., 347; Prain, *Beng. Plants*, 1903, ii., 1075; Cooke, l.c. 768; LILIACEÆ. Indian Squill, *kauḍā*, *jangli-piyāz*, *iskil*, *phaphor*, *kochinda nari-vengāyam*, *nakka vulli-gadda*, *adavi-irullī*, *kāttullī*, *to-kesūn*, etc. A bulbous herb found in the drier hills of the Lower Himalaya and on the Salt Range, ascending to about 6,000 feet in altitude. It is a larger plant than the preceding. Is considered an efficient substitute for the genuine squill (*Urginea scilla*). But there are several other species of *Urginea* met with in India, and these are doubtless used in some cases as inferior grades. The most general substitutes or adulterants for the above are *Critium asiaticum* and *latifolium*; *Dipcadi unicolor*; *Pancratium triflorum*. [Cf. Pharmacog. Ind., iii., 1893, 476-9; Rept. Proc. Cent. Indig. Drugs Comm., i., 1901, 125, 233, etc.]

teatite.

Soapstone.

Polstone.

According to Holland, "there is a trade" in this substance "of undetermined value in nearly every province, but it is impossible to form even a rough estimate of its value." Again, he states that "the returns, which are confessedly incomplete, give an average annual production in India of about 35,000 tons, valued at £1,900."

OCCURRENCE.—Steatite is said to be one of the most widely distributed minerals in India, occurring very commonly in metamorphic rocks. The provinces in which good qualities chiefly occur are Madras, the Central Provinces, Rajputana and Burma. The following gives a brief summary of the supplies:—

Occur-
rence.

Madras.—The best forms are met with in Betumcherla and near Maddawaram village in the Karnul district. After that, the soapstones of Anantapur, North Arcot, Bellary, Cuddapah, Salem, Malabar, Vellore, South Kanara districts and Pudukotai State may be mentioned. In 1896 a request was made that a consignment of some 20 tons from Maddawaram village should be furnished for trial as tops for gas-burners. The mineral was collected by local officers, under the superintendence of the Geological Department, and shipped to England. It was found, however, that nearly the whole of the consignment was useless for the purpose contemplated. In 1899 the quantity produced in Madras is stated to have amounted to 103 tons, valued at Rs. 4,900. [Cf. Foote, *Rec. Geol. Surv.*, 1895, xxv., pt. 1, 33-5; *Mem. Geol. Surv.*, 1895, xxv., pt. 3, 203; Francis, *Dist. Gaz. Mad.*, Bellary, 1904, 20, 255, 294; *Anantapur*, 1905, 11, 196.]

Madras.

Gas-burners.

Central Provinces.—The marble rocks in the Jabalpur district and Kanheri in the Bhandara district are said to yield excellent stone. According to a report by the Deputy Commissioner of Bhandara, the quarry at Kanheri was leased in 1898 by Government for Rs. 118, the output being approximately 2,000 maunds of stone. "This stone is used for making cups and other vessels, and there are about 10 factories called '*jantar*' all in the above village at work for making

O. Prov.

Cups.

them." "The business is carried on for eight months of the year, of which half the period is given to extracting and dressing the stone for work and the other half is spent in making cups in the '*jantar*.'" The outturn in 1900 was 82 tons.

Rajputana.

Rajputana and Central India.—The stone occurs in the Jaipur State of Rajputana, at the villages of Mora, Raiwala and Gisgarh. The mineral at Mora is pale green and finely crystalline, and is largely used at Agra for manufacturing elaborately carved ornamental articles. The mineral also occurs in the Bandelkhand States of the Central India Agency, as, for example, at Orcha and Bijawar. The outturn in Central India in 1900 is said to have been 68 tons.

Burma.

Burma.—There are mines in the Prome, Pakókku, Katha, Bhamo, Kyaukpyu and Minbu districts. The Minbu quarries and those in Kyaukpyu district are all in a group on the borders of Arakan and Upper Burma. In 1896 those of Minbu were reported on by Hayden, according to whom there are two chief localities where steatite is worked—(1) some 30 miles west of the village of Hpaaing, and (2) near the village of Senlan in Ngapé township. The total number of mines in the first locality amounts to about 26, but only 4 were being worked at the time of Hayden's visit in 1896. In the second locality, according to the same writer, there are 9 pits in all, but only a few yielded sufficient steatite to be worth working. In 1900 the outturn of steatite in Burma is reported to have been 51 tons, valued at Rs. 10,131. [*Cf. Rept. Dist. Prod. in Burma, Rev. Dept., Sept. 1888, No. 154-27 M; Rec. Geol. Surv. Ind., 1897, xxx., pt. 1, 6; Scott, Gaz. Upper Burma and Shan States, 1901, ii., pt. 1, 305.*]

Uses.

Uses.—There is a large demand for steatite in India, chiefly for the manufacture of bowls, plates, cups, fancy boxes, etc. Many ornamental articles, such as paper-weights, pen-holders, etc., are also made of it. It is largely used in the manufacture of idols, and a special form found at Mysore has, owing to its suitability for this purpose, received the name of *pratima kaller*, or image stone. Many temples and palaces also contain ornamentations of sculptured steatite. Ground to powder it is commonly employed as a white ink, or is added to plaster (*e.g.* the *chunam* or lime-plaster of Hyderabad) to make it shine (see p. 714). In Burma, pencils are made of it and used for writing on black-paper slates. In Madras Presidency, Cuddapah soapstone is largely used for polishing *chunam* walls. Out of India it has come into prominence through the property it possesses as a pigment of protecting steel against corrosion. Mixed with a quick-drying varnish, it produced a paint of great covering capacity and firmness. Owing to its refractory nature, it is largely employed in the manufacture of gas-burners and crucibles. It is reputed to be almost unaffected by atmospheric agencies, and in China is commonly used to preserve structures built of sandstone or other substance liable to disintegrate.

ASSAM INDIGO

T YC O
UX-VO ICA
Strychnine Tree

S. urens, Roxb. The *gūtā*, *kanrai*, *odla*, *tabsu*, *vellay pūtali kavalec*, *pandruk*, etc. A large deciduous tree of the dry forests of Northern India; throughout Central India and the Deccan; common on the west coast in the Konkan and Kanara; as also the dry forests in Burma.

It yields a GUM, called *katila* or *katira* (see p. 95), which is of the tragacanth or bassora or "insoluble" series, and has been used in the Bombay hospitals as a substitute for tragacanth. Guibourt (*Pharm. Journ.*, 1855, 15, 57) has observed that the gum gives off acetic acid when exposed to moist air, and that consequently it develops an odour of vinegar when kept in closed bottles. The origin of this acetic acid in a similar gum from Australia has been investigated by Robinson (*Journ. Chem. Soc.*, 1906, lxxxix., 1496). From the bast a good FIBRE is procured and made by the Natives into ropes and coarse cloth. "The bark is obtained when the trees are over ten years old. The trees are cut down, and after lopping off the branches, the trunk is cut into pieces, six feet long, from which the bark is separated by making a perpendicular incision" (*Ind. Text. Journ.*, Aug. 22, 1894, 265). Gum, leaves and branches are all employed in Native MEDICINE, and the seeds are roasted and eaten by the poorer classes. Gammie (*Rec. Bot. Surv. Ind.*, ii., 177) states that the roots are also edible. "They are first cut into small pieces, then boiled and mixed with either spices or sugar." The twigs and smaller branches are used as cattle FODDER, especially in times of scarcity (Indraji, in *Ind. For.*, 1900, xxvi., 167). The WOOD is made into guitars and toys. [*Cf. Pharmacog. Ind.*, 1893, iii., app., 129-30; Cameron, *For. Trees of Mysore*, 1894, 32; *Agri. Ledg.*, 1901, No. 9, 346.]

Timber.

S. villosa, Roxb. The *udal*, *gul-bodla*, *poshwa*, *kamhlyem*, *baringa*, *buti*, *omak*, *yake nar*, *sisi*, *savaya*, *shawni*, etc. A moderate-sized tree of the Sub-Himalayan tract from the Indus eastwards: common in forests throughout India and Burma. It is valuable on account of its FIBRE, which is coarse and strong but made into ropes and bags. In Southern India and Burma it is said to be much esteemed for making elephant-ropes, and in Northern India for cattle-halters. [*Cf. Agri. Ledg.*, 1894, No. 12, 202; Cameron, *l.c.* 32-3; Dodge, *Useful Fibre Plants of the World*, 1897, 305; *Kew Bull.*, 1897, 8; Nisbet, *Burma under Brit. Rule and Before*, 1901, i., 371, 384; Hooper, *Rept. Labor. Ind. Mus.*, 1905-6, 35-6.]

TRO ILANTH FLACCIDIFOLIUM, Nees; *Fl. Br. Ind.*, iv., 468; *Bot. Mag.*, 1887, 6947; Gamble, *Man. Ind. Timbs.*, 519; ACANTHACEÆ. The Rûm or Assam Indigo Plant, *râmpât*, *bar-rum*, *khuma*, *sapro*, *chimohu*, *tonham*, *mai-gyee*, etc. A shrub of North and East Bengal, Assam, Manipur, and distributed to North Burma and Southern China.

D. P.,
vi., pt. iii.,
375-7.
Rû .

This plant yields the *rûm* DYE of Assam and is probably the source of much of the so-called indigo of Burma (see Indigofera, p. 663). It is fairly generally cultivated, for the purpose of obtaining the dye, by the hill tribes throughout the region of its distribution. The plant is propagated freely by root cuttings made in May or June or earlier if the rains set in. It yields prunings twice or three times a year, and is perennial. The two chief crops are in April or May and again in September or October. Mr. Srijut Lakhi Nath Kakoti, a sub-Deputy Collector in Assam, has recently contributed an interesting paper on the cultivation of *bar-rum*. He speaks of one *cottah* of land yielding 8 to 10 seers of the dye. The Native methods of utilising the dye are fully described in the *Dictionary*. [*Cf. Duncan, Monog. Dyes and Dyeing in Assam*, 1896, 48-50; *Rec. Bot. Surv. Ind.*, i., 221, 257; Hosie, *Rept. on Prov. Ssu'ch'uan, China*, 1904, No. 5, 43-4.]

forests in the Bombay Presidency; deciduous forests all over Burma; dry regions of Ceylon" (Gamble).

Seeds.
Nux-Vomica.

The tree is important as being the source of the alkaloids, STRYCHNINE and BRUCINE, which are obtained from the SEEDS. The fruits are collected and the seeds washed out and dried in the sun, or the seeds are simply gathered from the ground, but in the latter case have little market value. They are roundish, flat or concavo-convex and silvery in colour. "Cochin nux-vomica is collected in the dry deciduous forests at the foot of the Travancore hills and is sold to small Native dealers at a low rate, who send it to the merchants. Coconada nux-vomica is obtained from the Ganjam district and the Godavari. The Madras seeds come from Nellore and several other parts of the Presidency" (*Pharmacog. Ind.*, ii., 500). "The London market quotation is usually about 7 to 10 shillings per cwt. The exports are chiefly from Madras, Bombay and Cochin, and are of considerable amount" (Gamble). In addition to the alkaloids just mentioned, they yield a DYE, which produces light brown shades on cotton cloth, and an OIL employed medicinally by Native practitioners. By the hill tribes of the Nilgiris they are used as a fish poison and are employed by Native distillers, who add small quantities to *arak* to render it more potent (p. 1047). The bark and wood also contain brucine and are employed medicinally in India. The

Dye.
Medicinal Oil.

Wood.

WOOD is said to be used in Burma for making carts, agricultural implements and for fancy cabinet work. [*Cf. Paulus Aegineta* (Adams, transl. and Comment.), 1847, iii., 358-60, 461-2; Fryer, *New. The Resin = *lubán* (Ind. bazárs), *hussí*, *shambiráni*, *kaminian*, etc. A small tree of the Malay Archipelago, important as yielding the true Benzoin or Gum Benjamin of commerce.

Origin.

This substance appears to have been first mentioned by Ibn Batuta (*Voy.*, etc., Fr. ed. 1858, iv., 228, 240), who visited Sumatra (A.D. 1325-49). He calls it *Lubán-Javi* (= incense of Java), the name Java being used among the Arabs and Persians of that time for the Eastern Archipelago. According to the *Pharmacographia Indica* (iii., app., 169) there are four kinds of the resin met with in the London market, viz.:—Siam, Sumatra, Penang and Palembang. It is well known that the present species is the source of the Sumatra resin, but there is considerable doubt regarding the plants which yield the other three sorts. The Siam resin is the costliest and most esteemed, and is imported by India in cubic blocks which take their shape from the cases in which packed while still soft. The resin is largely used both in India and Europe in MEDICINE, as an INCENSE and as a source of *benzoic acid*. The import trade is considerable, amounting in 1905-6 to 16,090 cwt., valued at Rs. 4,14,649. Almost the whole comes from the Straits Settlements, viz., in 1905-6, 16,074 cwt., and goes chiefly to Bombay, 9,717 cwt. in the year named. Exports of the resin in 1905-6 amounted to 52 cwt., and re-exports to 1,394 cwt. [*Cf. Varthéma, Travels*, 1510 (ed. Hakl. Soc.), 1863, 234; Garcia de Orta, 1563, *Coll.*, ix.; also in Ball, *Proc. Chiretta.

The dried plant (stems, leaves, flowers, roots, etc.) has long been held in
esteem by the Natives of India. It is possessed of tonic, febrifuge and laxative
properties and is officinal in the *British Pharmacopœia*. It is collected when the
capsules are fully formed. The plants, pulled up by the root, are tied into
flat bundles with a slip of bamboo. Most of the commercial article is said to
be collected in the Morung district of Nepal, and seems to find its way largely to
Dacca. The bundles are packed in bales, each containing about 1 cwt., and
exported to Calcutta, thence distributed all over India and to the rest of the
world. In India the true drug is said to be sometimes confused with the Creat
(*Andrographis paniculata*, *Nees*), and in some localities another species, *s. an-
gustifolia*, very inferior to the genuine article in its bitter tonic properties, is
used as a substitute. [*Cf. Pharmacog. Ind.*, ii., 511-5; *Waring, Baz. Med.*

láksh, *lák*, *gálá*, *arakku*, *ambalu*, *khejijik*, etc. *Lákshá* or *rákshá* and *alakta*
(= washed lac), the Sanskrit names, are apparently the source of most of
the vernacular names for both the insect and its products. Thus stick-
lac is *kham-láksh*; seed-lac, *dáná-lakh*; shell-lac (or shellac), *chapra-láksh*,
and lac-dye, *kirmai*.

istory.—There can be no doubt as to the lac insect and its name being endemic **History**.
in India. The insect is even to-day practically confined to India. But the word
lákshá in the *Atharvaveda* seems to denote *Butea frondosa* (p. 189), a tree upon
which it is not uncommon to find the lac insect, and which by the more recent
Sanskrit writers has come to be described as the *lákshá-taru* or lac-tree. The

Vedic description—the golden, the odorous, the hairy one, sister of the waters, etc.—might easily be viewed as appellations of *lākshā* (*Butea frondosa*) and indicative of its appearance, structure and habitat—frequenting as it does the margins of water-channels and creeks. But a vast antiquity being thus established for the Indian knowledge of *lāksh*, it is surprising that it finds no definite place in the ancient classic literature of Greece, Rome, Egypt, Persia and Africa. All the passages which, according to some dictionaries, are taken to denote a knowledge in lac, refer to a red-dye-yielding wood, or to *kermes* or to a resin at present unknown, but do not denote Indian lac. That substance was made known to Europe through the Arab traders, hence its being often called “Arabian” or “Ethiopian Resin.” If it was known to the ancient Greeks, their knowledge of it could not have much preceded the date of their discovery of India itself.

Dye and
Resin.

Lac yields two distinct products—a DYE and a RESIN. At first these were confused, but ultimately clearly and separately recognised. In the *Periplus* (written somewhere about 80 A.D.) “*lakkes chromatinos*” or lac-dye is mentioned as conveyed from India to Aduli on the African coast of the Red Sea. *Ælian* (*Nat. Hist. Anim.*, 250 A.D., iv., 46) describes lac as made in India from insects and employed a red dye. Pegolotti (*Della Decima*, 1343, iii., 365) speaks of “lacca” as Indian, produced on branches of trees. Nicolo Conti and also Nikitin (in the 15th century) mention, as if an important commercial product, the “lacca” of Cambay. Varthéma (*Travels*, 1510 (ed. Hakl. Soc.), 222, 238) discusses the “lacca” of Pegu, also the “lacca” wood of the Malay. The former is the true lac, the latter a red-coloured wood exported from Sumatra (Crawford, *Dict. Ind. Islands*, 1856, 204). Garcia de Orta was perhaps the first European, however, who critically examined and described lac in India, and he gives the properties and uses of both the dye and the resin in such detail that the passage might be quoted as from the pen of a 20th instead of 16th century writer. As physician to the Portuguese Governor of India, he visited that country in 1534. His volume of *Colloquies* was published at Goa in 1563 and was the second book printed in India. He there (*Coll.*, xxix; also in Ball, *Proc. Roy. Ir. Acad.*, 3rd ser., i., 414) criticises the accounts given by Isaac (a physician of Bhagdad, who was crucified in 799 A.D.), by Serapion (who lived about 850), and by Avicenna (whose works are assigned to 980–1036). These early Arab writers, Garcia tells us, called it “laca,” “luc,” etc., but confused it with the *cancamum* (the resin known to the Greeks to which reference is made below) and ultimately with the dye *kermes* of the Greeks. They were in error, he observes, in regarding it as an Arabian or Armenian product—a circumstance which Garcia very rightly accounts for by the Indian supply on reaching the Red Sea and Persian Gulf ports being subsequently designated by the name of the port from which procured. Many writers confused a red-dye wood, such as logwood or sappan-wood, with lac, and one of these red-dye woods, as just mentioned, actually bears the Malay name of *laka*. Gaspar (*Purchas’ Pilgrimes*, iii., 177) alludes apparently to the same wood under the name *cayolagne* (? *kayū* = wood and *lakh*). If this be so it is possible it was so named because employed as a substitute for the true lac-dye. “Lac” and “lacquar” wood and dye are words frequently mentioned, when there is nothing to show that they denoted Indian lac—resin or dye—as understood to-day. Every page that contains the word “lac” cannot therefore be accepted as of necessity denoting the *lakh* of modern Indian commerce.

European
Travellers.

Arab Writers.

Red-dye Wood.

Cancamum.

Dialacca.

Linschoten and most European travellers in India, subsequent to Varthéma and Garcia, content themselves with compiling from the latter, without adding anything of value as the result of personal observation. Some few years previous to the appearance of Garcia’s *Colloquies*, however, an interesting passage on lac had been published by Amatus Lusitanus (1553) in his *Commentary on Dioscorides* (book i., ch. 23, 44), the passage regarding *cancamum*. Amatus there repudiates all idea of lac being the classic gum of the Greeks, whatever that may have been. He then adds that lac was being brought from India by the Spaniards to be used as a dye and also in the fabrication of the Arabian medicinal preparation known as *dialacca*. We next hear of lac through Mathiolus (1565), who in his commentary on the *cancamum* of Dioscorides, tells us that lac was being largely used by the Italians as a silk dye called *lacca* or *lachetta*, the best quality of which was in the trade designated *lacca sumetri*. By Clusius (1567–1605, compiling largely from Acosta (*Tract. de las Drogas*, 1578, 113) and other subsequent writers, we are told that it had become customary for lac to be consigned from Pegu to Sumatra in exchange for pepper, hence its being designated Sumatran Lac.

To this circumstance is due also the fact of its being often mentioned in lists of spices in place of among dyes or resins. Acosta supplemented, however, Garcia de Orta's account by the interesting particular that the resin lac was mixed with, or, as he calls it, adulterated with, common resin and wax. Thus then the adulteration in recent years, often much complained of by the trade, is not a product of the greed of modern commerce. Mandelslo (*Travels*, in Olearius, *Hist. Muscovy*, etc., 1639, 27), speaking of the lacquer work of Gujarat, says, "They give them such a lustre as none yet could ever imitate in Europe." Tavernier (*Travels Ind.*, 1676 (ed. Ball), ii., 281-2) observes that—"The country also produces an abundance of shell-lac. There are two kinds of it. That which is formed on trees is of a red colour and is what they dye their calicoes and other stuffs with, and when they have extracted this red colour they use the lac to lacquer cabinets and other objects of that kind, and to make Spanish wax. A large quantity of it is exported to China and Japan." Thevenot (*Travels in Levant, Indostan*, etc., 1687, pt. iii., 112) repeats the statement that lac was exported from Pegu. Lastly, Salmasius (*Pliniana Exercitationes*, 1689, 810) asserted that the very name "lac" had been derived from the Greek and originally denoted a red wood. He arrived at that conclusion chiefly through his own supposition that the Indian name for the substance was *trec*, not *lakh*. *Trec* is doubtless a variant of the Pegu name *cheik*, and, as already abundantly indicated, was carried to Europe through the Spanish trade between Burma and Sumatra.

While a knowledge in lac was thus being gradually disseminated over Europe, there are not wanting indications that within India itself the subject was not being neglected. Thus in the *Ain-i-Akbari* (Blochmann, transl., 226), a work often spoken of as the administration report of the Emperor Akbar for the year 1590, we read of the proportions of lac resin and certain pigments to be employed in varnishing *chicks* or screens on the doors of public buildings. It would from that circumstance seem highly probable that a coloured spirit varnish may have been known and used in India long before Europe possessed any knowledge of that valuable substance. Fryer (*New Acc. E. Ind. and Pers.*, 1672-81, 83) also alludes to elegantly coloured *chicks*, but it may be added the modern *chicks* are crudely stained with mineral dyes, never with lac varnish.

The period of the struggle for European supremacy in the East was practically that of the birth of all definite knowledge in lac. But the scenes and the persons change rapidly and the interest shifts from the dye to the resin, back again to the dye, and finally once more to the resin. From the Portuguese on the west coast of India the trade passed to the Spanish and Burma *via* Sumatra, while a little later on (and in the hands of the British) it returned once more to Bombay. In the Records of the East India Company (*First Letter Book*, 1600-19, 338, etc.) we are given certain glimpses of the Company's instructions to their servants. "Gumlacre" was to be obtained from Cambay. "Gum lack" of first and second sort was to be procured at Surat, "but none of the worst of any hande." Private trade in gum-lac was prohibited. So again, of date 1616, "much gum-lac, both of the sort used for dyeing and also that of which wax is made" was to be purchased in Surat. The following year the "lack" of Baroda is said to be in "grains like mastic pure as amber." Of Agra it is observed there are two kinds: "The one is in small sticks usually carried hence to Mocha: the other is in great cakes. They both cost one price, viz., 8 rupees per maund." The amber-coloured grains of Baroda were doubtless "washed seed lac," and the great cakes of Agra would imply manufacture. Is the *canna* (*kana* = grain) *lacke* mentioned in 1623 as purchased at Baroda simply washed lac? But in these early records of the East India Company there is apparently no mention of shell-lac nor of some of the chief centres of the present manufacture, such as Mirzapore and Calcutta—but of course the town of Calcutta was not in existence at the time indicated. The fact remains the same that the early records manifest localities of production that are quite unimportant compared with other more recent centres.

The demand for cochineal served the useful purpose of pointedly directing attention to the lac-dye. This, though inferior, was found quite good enough for most of the purposes to which cochineal was put, and had the additional advantage of being considerably cheaper. A large trade in lac-dye accordingly sprang into existence that gave the impetus for numerous lac factories owned directly or indirectly by the East India Company. At this time was invented (and by Europeans doubtless) the method of manufacturing lac-dye into special cakes ready for use. Such importance did this new industry assume that it dwarfed

the gum-lac of the earlier commerce until it might almost be said that the resin (lac) became a by-product of the lac-dye factory. To this circumstance is due the fact that the methods of cultivation, of collection and of manufacture, that exist to the present day, were invented and perfected with a view to produce the dye, one might almost say, at the expense of the resin. The dye gave the profits of the industry. But Sir W. H. Perkin's discovery of aniline struck at once the death-blow of both the Mexican cochineal and the Indian lac-dye industries.

By this time, however, new methods and directions of using the resin lac had been discovered in Europe, and the interest of the factory shifted until the dye became first the by-product and ultimately the useless or waste material of the factory. Here then we are presented with a demonstration of the startling fact that a by-product that can be produced at an almost nominal cost cannot of necessity contest the market against the products of the chemical laboratory. Attention was thus concentrated on the resin, and it soon became the chief feature of interest. James Kerr (*Phil. Trans.*, 1781, lxxi., 374) was one of the first to mention and describe the manufacture of shell-lac. From about that date, therefore, the modern factory industry may be assumed to have originated. In the story of lac we have once more a demonstration of the indebtedness of India to England for her modern commerce.

ORIGIN OF LAC.

Life-history of the Insect.—The minute Hemipterous insect *Tac-hardia lacca* lives upon the plant juices sucked up by a proboscis. In the adult state the females have no power of locomotion, but the males on attaining maturity emerge from their pupal cases, become possessed of a pair of long transparent wings, and fly away to visit the females and shortly after die. At two (in some cases three) seasons the swarming of the larvæ takes place, viz. July and December or also January. The larvæ are seen to emerge from the dead bodies of the females and to crawl away in quest of fresh feeding grounds. They are then minute creatures of an orange-red colour, have no recognisable separation of body into head, thorax and abdomen, have fully formed feelers and powerful legs, but are devoid of any characteristics by which they can be separated into male and female. They measure about one-fortieth of an inch in size. For some days the swarming continues until the twigs become distinctly reddish in colour and literally alive. The vast majority, however, perish; the more fortunate are wafted on the breezes or are carried by the bees, birds, squirrels, etc., or by their own exertions, to new situations. The larvæ thus becomes fixed, and their legs, being useless, drop off. Lastly, a resinous excretion begins to form around their bodies, which by the aggregation of many in time assumes the condition of a more or less complete encrustation of the twigs. If at this stage the encrustation be cut open lengthwise, it will be seen to be of a cellular structure and to comprise two kinds of cells—large circular caverns and smaller oval cells. The former will, moreover, be noted to be much more numerous than the latter. The circular cells are the females and the oval ones the males.

About two and a half months after the swarming, the males escape from their cells, become (as already stated) winged, and fly or flutter away to visit the females. Shortly after this the bodies of the females become greatly enlarged, assume a bright red colour, and in due course develop viviparous larvæ. The mother then dies, her body becomes the resting chamber of her offspring (about 1,000 in number), which at their appointed time make their escape by swarming, and thus twice (or it may be thrice) a year this strange cycle of life is repeated.

PRODUCTION OF LAC.—The system of propagation that at present prevails consists in lopping off a few twigs of well-formed lac, a little before the expected date of swarming. These are carried to fresh trees or fresh

boughs of the same tree and tied in convenient and suitable positions. The larvæ on swarming crawl to new wood and become fixed. If the object in the collection of lac be to procure the red dye, the stick-lac (that is, the lac-encrusted twigs) should be gathered before the larvæ have swarmed. But if the resin-lac be sought, there would seem every reason to delay collection until the swarming has taken place. The industry assumed its present form while lac-dye (if not equally valuable with the resin) was a profitable by-product. It is now valueless; its presence admittedly depreciates the shell-lac very greatly; it necessitates expensive and possibly to the resin injurious methods of removal; and the decomposition of the larvæ gives the offensive smell to the factory, which well-nigh becomes a public nuisance. It would therefore seem that the time has more than come when this state of affairs might be mitigated by some change in the season of collection, that would allow of the colour being very largely removed before the stick-lac comes to the factory. The collecting seasons at present adopted are May to June for the one brood and October to November for the other; a delay of a month or six weeks in each case would see the swarming accomplished. [Cf. with opinion of Hooper, *Rept. Labor. Ind. Mus.*, 1906-7, 7.]

I prove ent in Quality.—There would seem to be little or no doubt that in India there is not one species of *Tachardia*, but several. The well-known different qualities of lac are due, it has been said, to the plants on which the insects feed. This is, however, likely to receive an even more rational explanation, viz. that the grades of lac are due to being the resins of different species of insect. It is also well known that the forms of lac found on leguminous plants (or on soft-wooded plants), such as *Butea frondosa* and *Cajanus indicus*, can with difficulty be induced to live upon hard-wooded trees, such as *Schleichera trijuga* and *Shorea robusta*, upon which lac is nevertheless found. But there is still a further consideration of importance. It has been observed that there are special cultivated races, such as those found on *Acacia arabica*. In Sind and adjacent tracts that plant is used as a food-stock, but hardly anywhere else is lac to be seen on that tree. We have here either a special race or a remarkable climatic adaptation. Further, all over India albino-broods have been recorded as occasionally seen. It would thus appear that were the selection of stock placed on a rational and scientific basis vast improvements in quality might be effected, if it were not possible actually to evolve a white insect or at all events one to a large extent devoid of the objectionable colour, the removal of which so seriously enhances the cost of the present-day resin.

Food of the Lac Insect.—The insect lives upon a large number of widely different plants. In *The Agricultural Ledger* (l.c. 210-3) I have given a list of some 56 trees. Those best known are *Butea frondosa*, *Ficus religiosa*, *Schleichera trijuga*, *Shorea robusta* and *Zizyphus Jujuba*. These are all indigenous Indian trees, so that the lac obtained from them may be called wild lac (the insect being at most semi-domesticated); but two plants are specially grown for it, and where this is the case, the lac may be regarded as a plantation product and accordingly spoken of as existing under a greater degree of cultivation than the wild insect. The plants specially grown are *Acacia arabica* in Sind, Rajputana and Gujarat; and *Cajanus indicus* in Assam. But lac does not, in many localities at least, pay as a special plantation product. The

Capricious Crop. crop is most capricious both in yield and price. One year it may be highly profitable, the very next sold on so narrow a margin that no inducement exists for extension. In support of this statement, witness the fact that in 1902-3 the exports of shell-lac were 195,000 cwt., valued at 15½ million rupees (£1,048,991), while next year, 1903-4, they were only 178,000 cwt. but were valued at over 21 million rupees (£1,456,067). That is to say, while there were 17,290 cwt. less exported, the sum realised was nearly half a million pounds sterling more in 1903-4 than in 1902-3. And the fluctuation might just as likely have been toward a loss as a gain of half a million in the sum realised. No other item of Indian trade manifests anything like such extreme fluctuations in price as lac, and it can, therefore, be no matter for surprise that the supply should correspondingly fluctuate.

Extreme
Fluctuations.

Climatic
Influences.

LOCALITIES OF SUPPLY AND COST OF PRODUCTION.—Lac is met with practically throughout the warm tropical areas of the whole of India, but most abundantly in the Central Provinces, Bengal, Assam and Burma. In Sind and Gujarat, as already stated, the *babul* tree (*Acacia arabica*) may be said to be that on which it is met with most abundantly. In Bengal, where both the *babul* tree and the lac insect are plentiful, it is extremely rare to find lac on that tree. But, as already suggested, the question naturally arises, is the *babul*-feeding insect of Sind the same species as the *palas*-feeding one of Bengal and the Central Provinces? The climates and soils of Sind and Bengal are about as different as it is possible to imagine, although both are tropical. The one is extremely dry, the other extremely moist, and that alone may account for the behaviour of the insect.

Climates.

Cost.

Cost of Production.—Mukerji (*Handbook Ind. Agri.*, 1901, 496) gives the following calculation of expenditure based on an actual experiment conducted by an Assam planter :—

Rent at Rs. 3 per acre for 80 acres	Rs.
Hoeing or cutting jungle between trees	240
Upkeep of necessary buildings	100
Cutting branches and putting in seed	340
					<hr/>
					Rs. 1,000
Manufacturing charges at 5 per cent.	3,500
Packing and dispatching at 2½ per cent.	1,750
Calcutta charges for forwarding and river freight, at 2½ per cent.	1,750
London charges for sea freight, Dock and Broker's charges	3,000
					<hr/>
				Total ..	Rs. 11,000
Proceeds of Sales, £1,750 at 14d.	26,250
Deduct discount to buyers	656
					<hr/>
				Total ..	Rs. 25,594
Deduct Expenditure..	11,000
					<hr/>
Balance of profit	Rs. 14,594

A Liary to
Tea.

"Lac worked in connection with tea, etc., the amounts for European and Native supervision and upkeep of coolie lines, etc., may be added proportionately according to circumstances. The planter referred to, however, lost nearly his whole crop next year from the attacks of a night moth."

KHASIA AND GARO HILLS

TAC A A

Production
engal.

Bengal.—According to the *Administration Report* (1901-2, 31), “it is found over the large tract of hilly country covering the Chota Nagpur Division and overlapping the west of the Bardwan and the north of the Orissa Divisions. The principal lac factories are in the districts of Ranchi and Manbhum in the Chota Nagpur Division, and in the Bankura and Birbhum districts in the Bardwan Division. Stick and shell-lac are largely exported from Ranchi, Manbhum and Bankura.” It is also stated that “the manufacture of shell-lac is an important industry in the Bankura district, and is chiefly carried on in the town of Sonamuki. The main supply of this article for all the factories in Bankura is obtained from the districts of the Chota Nagpur Division. The industry is carried on to a large extent at Elambazar, in Birbhum. Shell-lac and lac-dye are also manufactured at Mankur and Degnuggur in Bardwan; but the industry is on the decline here also. There is a lac factory at Cossipore in the suburbs of Calcutta.”

Bankura.

Birbhum.

Cossipore.

Assa .—In 1900, Basu (*Agri. Dept. Indust. Bull.* (ser. 1), 1900, No. 6) wrote an account of the lac industry of Assam, from which the following may be abstracted. “Kamrup and the northern part of the Khasia and the Garo hills bordering on the Brahmaputra valley are at present the chief seats of its cultivation. In Kamrup lac-rearing is chiefly confined to the south bank of the Brahmaputra, the annual outturn of stick-lac in two *mauzas* (Rani and Chhayani) being estimated at about 2,000 maunds. A small quantity is reared by a few Kachari families in *mauza* Jhargaoon on the north bank. The bulk of lac exported from the district is, however, obtained from Garos inhabiting the northern slopes of the Khasia hills, who are said annually to bring in about 2,000 maunds of lac to the weekly markets at Palasbari and Chhaygaon and about 300 maunds to the markets at Boko. A small quantity of lac, averaging about 400 maunds a year, is brought in by Bhutias to the annual cold-weather fairs at Darranga and Subankhata in the north of the district.”

Assam

Kamrup.

Garo_Khasi.

Bhutia.

“In the Garo hills lac-rearing is chiefly confined to the north and north-eastern parts of the district, comprised in the northern range of the Garo hills Forest Division. The people of the south and south-western parts are said to have a superstition against lac cultivation. The annual exports of crude lac from the northern range is estimated at 1,300 to 1,400 maunds. In 1894 the Assistant Conservator of Forests, Garo hills Division, estimated the annual production and export at 2,000 maunds, and reported a serious decline in the cultivation of lac, which he attributed partly to the low prices and partly to the depopulation of the district through *kala-ázár* and migration. Considering that the bulk of lac exported from the Brahmaputra valley is the produce of the Kamrup and the Khasia and Jaintia hills and the Garo hills districts and that the exports have during the past five years averaged over 16,000 maunds a year, the foregoing estimates of outturn of lac in those districts would seem to be much below the truth.”

Superstition.

Annual
Production.

Central P vinces.—The lac insect is found throughout the Central Provinces, but the main centres of collection are the Jabbalpur, Saugor, Damoh, Nagpur, Raipur, Bilaspur, Sambalpur, Chanda and Mandla districts. A *Note on the Lac Industry of the Central Provinces* (*Bull.*, 1902, No. 8) gives useful particulars regarding production. The lac-collector and sellers in these provinces were given in the census as 2,592 persons. Of the amount collected by far the greater part is exported, only a small

C. Prov.

Exports.

quantity being retained for local use. During the five years ending 1900-1 the exports fluctuated very greatly; in 1899-1900 they came to 99,961 maunds, valued at Rs. 11,96,394—the highest return in point of quantity—and in 1898-9, 39,713 maunds, valued at Rs. 5,42,391, the lowest record for the period mentioned. These exports, moreover, were almost entirely from Jabbalpur and Chhattisgarh, and were consigned to the United Provinces almost entirely, thus feeding the Mirzapore factories.

Burma.

ur a.—The large forests of Burma are said to be capable of producing an almost unlimited quantity of lac. The chief sources of commercial Burmese lac are the Shan States and Upper Burma, stick-lac from these places being imported into Calcutta, where it is manufactured into shell-lac for export. For some years the supplies received by the Calcutta factories from Burma have begun to be appreciated as important. According to Sir J. G. Scott (*Gaz. Upper Burma and Shan States*, 1900, ii., pt. 1, 393), though lac is found all over these States, it seems to be only in Karen-ni that its production is stimulated artificially. "Elsewhere if a tree happens to be attacked, or settled on by the insect, the deposit is collected when it is found."

Exports to Calcutta.

MANUFACTURE OF LAC.

Manufacture.

Lac Factories.—In the *Imperial Gazetteer* (1905, iii., 173-4) it is stated that though steam power has been successfully applied to the industry, the hand-labour factories still hold their own and for some grades produce qualities hardly, if at all, attainable by machinery. Lac factories are almost confined to Bengal and the United Provinces. In 1904, according to the *Financial and Commercial Statistics*, there were 128 lac factories giving employment to 7,831 persons. Of these 92 were in Bengal and employed 4,116 persons; 36 in the United Provinces, employing 3,715 persons. The number in Bengal is said to be not fully recorded. With the exception of the factory at Cossipore they are, however, in most cases small. Those in the United Provinces are all situated at Mirzapore. The value of the manufactures turned out has been stated at about two-thirds the total foreign exports, while the very large Indian consumption has to be met, and thus mainly by small factories possibly not included in the above returns.

Factories.

Stick-lac.

Seasons.

Stick-lac.—*Stick-lac* is the name given to the twigs encrusted with lac that are collected from the trees in May to June and the second crop, October to November. These are dried in the shade, by which the wood shrinks, thus often leaving the lac as hollow tubes, but much of the wood still adheres. It is packed in sacks and conveyed to the marts, and sold through various brokers or middlemen to the manufacturers. There is a quaint practice usually followed in most sales of lac. The buyers and sellers join hands and sit facing each other, a cloth being thrown over the hands. The buyer presses certain fingers of the seller's hand, thus making an offer. This is usually rejected by a motion of the head, and further finger-pressing ensues. Finally the bargain is struck without a word having been uttered.

Method of Sales.

Seed-lac.

Washing.

Seed-lac is stick-lac crushed and reduced to roundish pieces that more or less correspond to the female cells. The dust produced, when sifting the seed-lac, is known as *khud*. The pure seed-lac is then washed in large stone troughs and left covered over with water for 24 hours. The wood floats to the top and is removed, dried, and used as fuel. A man or woman

now enters the trough and, while holding on to a transverse bar placed at a convenient position, treads with the bare feet on the granular lac and presses it against the sides of the trough. As a result the lac is broken into still finer particles and the water becomes of a deep claret colour. The coloured water is run off, a fresh washing given, and repeated till the washings pass off colourless. The washings, if it be so desired, are evaporated down to a thick consistence and compressed into cakes. This is lac-dye. The resin is now called *washed-seed-lac*, but it is sifted into two qualities—granular and dust; the latter is called *gaud*. When steam machinery is used, the washing is done with revolving cylinders and beaters.

Lac-dye.

In some parts of India the seed-lac is now either washed or even boiled in a solution of crude carbonate of soda or of soda and borax, or of crude carbonate of potash, or of borax alone or of alum. After several such washings it is said to become almost white. But in most of the larger factories, especially those concerned in the production of shell-lac, the washing or boiling in alkaline preparations is dispensed with; the seed-lac is simply repeatedly washed in pure water but not bleached. Indeed, according to some authorities, it is even maintained that bleaching weakens the lac. After being washed, or bleached and washed, to the desired extent, the seed-lac is spread out on special floors and exposed to light and air, by which it is thoroughly dried and still further bleached.

Bleaching.

According to the purpose for which intended, the dried washed lac is now mixed with either or both of the following substances—yellow arsenic (orpiment) and resin. The mixture is then fused either before an open fire or by steam-heating. Steam is practically confined to the European factories. The arsenic is said to make the lac opaque and to impart a rich straw colour to the shell-lac, but its action would appear to be mainly if not entirely mechanical. It is responsible for the opacity and rich straw colour of all the finer qualities of hand-made shell-lac. But the inquiry for a substitute for arsenic has often been made, though not as yet supplied. A yellow colouring material that will fuse into the lac when subjected to the temperature that corresponds to 35 lb. steam power is required. Arsenic is not, however, employed in the preparation of garnet or button lacs, nor other grades where fulness of colour is no disadvantage.

Addition of Arsenic or R

The object of the resin is to lower the melting-point, a condition essential for many industries and one known from fairly ancient times (witness Acosta's allusion to it in 1578). Its value, therefore, is fully recognised and a certain amount is not only admissible by the rules of the trade (2 to 5 per cent.) but few of the shell-lacs that are regularly exported can be said to be entirely free from resin. During seasons of high prices the proportion is often, however, raised until it passes from the condition of permissible admixture to what might be called criminal adulteration.

Requirements.

Object of Resin.

Lac Fusing.—The specially washed and bleached lac, mixed with its required proportions of arsenic and resin, is now (by the hand manufacture) placed within long narrow bags (20 feet by 2 inches). For one quality of lac A erican drill is necessary, for another a cloth specially made at the Cawnpore cotton mills is preferred, and for a third two bags are required, one within the other. After being charged the bag is arranged in front of a long open fire and so fixed up that it may be twisted the while it is being moved slowly along. The foreman operator sits on a little raised mud platform, on the immediate left of the fire and slightly behind it. With

his left hand he holds the end of the bag and resists the twisting action produced by his assistant. The fused lac, in the portion most exposed to the dry heat, is thus squeezed through the bag. Every now and then the foreman gives his end of the bag a reverse twist, and this causes the portion from which the lac has been removed to coil up like a rope. Steadily the bag is drawn forward as portion after portion is exhausted. With his right hand the foreman wields at intervals three weapons—one a long iron hooked poker with which he stirs the fire: a wooden spoon with which he every now and again sprinkles with water the tiled floor in front of the fire: and an iron scraper with which he removes the molten lac as it oozes on to the surface of the bag and allows it to drop on the damp floor. If not sufficiently cooked, the fused lac is picked up from the floor and placed once more on the top of the bag and fused again, and even two or three times. There seems to be great skill in knowing when the lac has been cooked to the proper extent. It is freely admitted that the hand-made lac possesses certain properties never attained by the steam-machinery factories.

Shell-lac.—The next stage is the production of shell-lac. For this purpose a mass of molten lac is handed to an assistant and placed by him on an earthen or zinc tube filled with hot water (or on a green banana stem) fixed in the ground at an angle of about 45° to the floor. By means of a ribbon of palm-leaf stretched between the hands, the assistant spreads the lump of molten lac into a thin skin perhaps one-eighth of an inch in thickness. But in this operation, which looks so simple, great skill is required in exercising just the right pressure to cause the lac to spread out in a compact sheet of uniform thickness. The sheet or skin is now clipped off the tube, trimmed into a rectangular form, and handed to still another assistant, who, carrying it in front of the fire, seizes it between his toes, teeth and hands, and widening his legs as he expands his arms and straightens his body and neck, stretches the sheet into three or four times its original size and reduces it to the thinness of tissue paper. It is then laid on a mat and allowed to cool gradually.

When quite cold the sheets are given to persons who assort them according to colour and break out all impurities and darker coloured portions. The rejections either constitute lower grades or are mixed with dark coloured seed-lac and used up in the manufacture of shell-lac where colour is no objection. In the production of garnet-lac, the sheets are taken at the hot-tube stage, no further stretching being necessary. Garnet-lac is very largely, however, the special product of the steam-power factories. As its name implies, it is of a deep rich red colour, and is in demand for industries where colour is not a disadvantage. In the preparation of button-lac the molten material is not stretched at all but is simply allowed to drop on to a smooth substance, such as a green leaf-sheath taken from the banana stem. Garnet and button lacs contain as a rule no arsenic, though they may possess a high percentage of resin.

The refuse that remains in the melting-bags is removed and the bag cleaned by being boiled in alkali. The refuse is then made into large circular cakes 6 inches in diameter and 1 inch or more thick. These are very possibly the "great cakes" alluded to by the East India Company procured in 1816 from Agra, as also the lump-lac of the early commercial returns. They are sold, like the *khud* and *gaud*, to the manufacturers of sealing-wax, bangles, toys, etc., and by the cabinet-makers such crude lacs are largely employed to cover up cracks in wood.

THE USES OF LAC.

Lac enters into the agricultural, commercial, artistic, manufacturing, domestic and sacred feelings and enterprises of the people of India to an extent hardly appreciated by the ordinary observer. The existence of the poorer communities, in the agricultural and forest tracts, is made more tolerable through the income derived from the collection of the crude article. Every village has its carpenter, cartwright, turner and shoemaker, and all these craftsmen use lac in some form or other every day of their lives. The blemishes and defects are plugged up and concealed by crude lac, and the surfaces are uniformly varnished or coloured with lac where colour is desired. Coloured lac, in fact, takes the place of the oil paint of Europe. The silver and coppersmiths employ it as a resist bed upon which to hammer out or punch certain of their wares. By means of lac, coloured ornamentations are made on copper and brass wares, as also on ivory. Lapidaries construct grindstones of the same material fused with sand and with it cement blade to haft in knives and swords (p. 695). Potters, bookbinders, and makers of smoking-pipes all need lac as a varnish or a stiffening material. Jewellers load hollow gold and silver ornaments with it, or fix the stones in these by its means. The makers of the humbler personal ornaments prepare most of their wares almost entirely of lac. Indeed it is highly possible that one of the very earliest utilisations of lac was this very preparation of peasant jewellery. Lastly, in the hands of the lac-turner and toy-maker lac is supreme. But let it be here observed it is desirable to call this lac-work and to reserve lacquer for the art practised in Burma and Japan, where a vegetable oleo-resin is the chief material, not the animal resin-lac.

Cement.

Lac and
Lacquer.

The turner (*kharādi*) with his lathe is met with in every village of India, and has an assured position in the community. He prepares toys, nests of boxes, bed-posts, *pāndāns*, *hukka* mouthpieces, and decorates agricultural and other implements, etc., etc. The pigments employed are orpiment, sulphur, white lead, red mercury, Prussian blue, lamp-black and indigo. Recently, however, aniline dyes have been much used, with the result that the delicate artistic colours have almost disappeared and the articles made at the present day fade and tarnish to such an extent as to render them no more desirable ornaments. Metallic results are produced by mixing the lac with powdered mica, with powdered tinfoil, with imitation gold leaf, or with an amalgam of mercury, lead and tin. These metallic materials, if used in large particles, give a quaint mottled appearance and simulate the grain of stone, thus often producing a rich effect.

Turnery

Colouring.

In the preparation of coloured lac, shell-lac is melted over the fire until it becomes plastic. It is then placed on a stone and a small quantity of pigment (previously dissolved in water or absorbed by oil) is deposited within a hollow formed on the surface of the lac. This is closed in and the lac hammered, then pulled out with the hands, doubled up, hammered, and pulled out again and again, until the colour becomes uniformly intermixed. The hammering communicates heat so that the mixture gradually assumes the consistence of india-rubber. The coloured lac is then formed into sticks the length and thickness of lead pencils, or thicker as may be desired. These sticks of sealing-wax, as they may be called, are known as *battis* and are the form in which both the lac and pigment are applied to woodwork. After the article has been prepared and smoothed, a *batti* is pressed against it as it revolves on the lathe. The heat generated melts the lac and thus colours the wood irregularly. The colour is then diffused by a small piece of hard wood pressed firmly on the revolving article. Lastly, a cotton rag, dipped in sweet oil (preferably *Sesamum*), is next applied to the revolving article, and this imparts a lasting polish to the lac surface. Obviously, therefore, the first conception in lac ornamentation must be a direct adaptation to a revolving object, hence the articles are either uniformly coloured in one shade or are ornamented by rings and bands of different colours. In the higher flights of lac-turnery and in the metal and ivory ornamentation with lac, however, a diversity and richness in effect are produced that have to be seen to be fully appreciated. The chief types of this work are designated:—

Battis.

Distributed by
Friction.

Methods.

1. Plain ornamentation.
2. *Abri* or Cloud Work.
3. *Atishi* or Fire Work.
4. *Nakshi* or Pattern Work.
5. Painted Ornamentation.
6. Tinfoil Ornamentation.
7. Lac Ornamentation to Metal Ware.
8. Lac Ornamentation to Ivory.

9 Value of Lac in Inlaying.

For timbers suitable for turnery and lac-work see *Buxus* (*Boxwood Substitutes*),
p. 190.

Timbers.

The reader who desires particulars regarding these various art utilisations should consult the special *Agricultural Ledger* mentioned above, as also *Indian Art at Delhi*, 1903. I have gone into the above details of Indian methods and experience from the belief that they throw some sidelight on the nature of lac. The systems of work mentioned are mostly very ancient. Barbosa, Garcia de Orta, Terry and other European travellers give such details regarding lac turnery, for example, that there can be little doubt the art was fully known three or four hundred years ago as it is to-day. But it is singular that no mention is made by any traveller of having seen lac factories in India, or even of the manufacture of shell-lac, till the early decades of the nineteenth century. It is not clear when and how that name came, in fact, into use. Pomet (*Hist. Drugs* (Engl. transl.), 1712, 202-4) describes the molton lac being (in Burma) spread out on marble surfaces, but does not call the article thus produced shell-lac. That name was, however, used by James Kerr in 1881 and by Vincent in his Appendix to the translation of the *Periplus* (ed. 1800, 25), so that it had by then come into general use. The production of lac in former times thus appears to have been a village craft practised all over India, which was most likely not concentrated into factories till the European demand arose.

Shell-lac.

Uses in
Europe and
America.

European and American Uses.—The uses of lac in Europe and America are similarly very varied. Perhaps its most important applications are in the manufacture of spirit varnishes (French polish) and in the supply of the chief material of sealing-wax. Large quantities are employed as a stiffening material in hat-making, as a cement, as an ingredient in lithographic ink; and as modern demands it may be mentioned that lac is largely employed in the manufacture of gramophone records, as an insulating material in electric appliances, etc. Through the last-mentioned utilisation a fresh impetus has been given to the traffic, which perhaps largely accounts for the recent expansion of the exports from India.

TRADE IN LAC.

Trade.

The first recorded exports of lac to Europe, as already stated, took place about 1607, but for nearly two centuries the traffic was entirely a Native commodity, as it had been still earlier (while in the hands of the Arab traders). Milburn (*l.c.* 217) tells us that the exports from India in shell-lac were in 1805, 2,377 cwt., valued at £12,978, and that in 1808 they stood at 239 cwt., valued at £1,243. The trade was thus not well established, and the expansion had been slow, for even in 1839 the total exports in "lac-resin" were only 7,226 cwt., and in 1840, 6,043 cwt. and, correspondingly, in 1839 the "lac-dye" stood at 4,756 cwt., and in 1840, 5,440 cwt. But in 1868-9 the shell-lac sent to Europe had reached a valuation of just under 12 lakhs (£80,000), and that of the lac-dye o 8 lakhs of rupees (£53,300). Since then the trade in lac-dye has gradually disappeared, while the exports of shell-lac have expanded to over two crore of rupees (£1,400,000 at present rate of exchange). This state of affair is, perhaps, best exemplified by the following table:—

Rise and Fall
of Lac-dye.

Progress of the
Resin.

LOCAL TRANSACTIONS

TAC A A
LACCA
Trade

I have not dealt with the button-lac nor with the unmanufactured forms of lac, since the exports of these are comparatively unimportant. The figures as they stand exhibit strikingly the way in which the traffic in the resin-lac has compensated for the loss of the trade in lac-dye.

Production and Local Traffic.—In the return of railborne traffic, lac is not treated under its separate headings, viz. of stick, seed, shell-lac, etc., but collectively. In 1906-7 the total quantity shown as exchanged came to 446,574 cwt. Of that amount, Bengal is exhibited as having exported 172,614 cwt., chiefly as follows :—122,155 cwt. to Calcutta, and 50,076 cwt. to the United Provinces. On the other hand, the United Provinces exported 134,356 cwt., almost entirely to Calcutta. Next come the Central Provinces with an export of 45,430 cwt., chiefly to the United Provinces. Lastly, Assam exported 35,159 cwt. entirely to Calcutta. It has already been shown that the lac factories of India are almost confined to Mirzapore in the United Provinces and to Calcutta in Bengal. This accounts for the traffic being toward these centres. But all over India small quantities are worked, so that the statistics of lac factories by no means convey a full conception of the Indian production and consumption. For example, the Indian dyers, when they use lac-dye, prefer to obtain it direct from the stick-lac, so that they are continually producing a certain amount of seed-lac, which they dispose of to the local dealers and lac manufacturers. It is, however, probably correct that the railborne traffic gives us the only satisfactory indication obtainable of the chief items of production. A total supply of 446,674 cwt. of stick-lac should be more than sufficient to furnish the raw material for the export of 205,473 cwt. of shell-lac. The production of the registered lac-factories is commonly believed to represent two-thirds of the actual production, so that one-third (or thereabouts) of the annual supply escapes all trade registration.

Produc-
tion.

Mirzapore and
Calcutta.

Share of
Registered
Companies.

Receiving Countries.—Another feature of importance may be here stated, namely the direct dealings of India with Europe and America instead of through the United Kingdom. The following classification of the returns for the past twenty-one years will exemplify this feature :—

Receiving
Countries.

Analysis of the Exports of Shell-lac from India.

	1885-6.	1890-1.	1895-6.	1900-1.	1905-6.	1906-7.
To :—	Cwt.	Cwt.	Cwt.	Cwt.	Cwt.	Cwt.
United Kingdom ..	72,463	56,391	76,793	55,689	51,699	43,837
United States ..	24,797	41,684	46,273	68,660	110,550	109,047
Continent of Europe ..	13,483	12,165	37,323	65,945	51,898	48,920
TOTAL (includes above and all others) ..	112,116	112,495	162,686	193,318	217,593	205,473

It will thus be seen that, while the exports from India have steadily expanded, the share drawn by the United Kingdom has not maintained its supremacy. America has become by far the most important single consuming country for lac, and what is still more remarkable, all the finer grade lacs go to the States and are purchased direct from the factories and not through Indian or British merchants. The traffic is, in fact, controlled by the United States dealing with the manufacturers direct. The possibilities of expansion are also extremely problematic.

Expansion of
American
Demands.

Future
Expansions.

THE TAMARIND TREE

The following statement classifies the foreign exports from India during the past three years :—

	1904-5.		1905-6.		1906-7.	
	Cwt.	Rs.	Cwt.	Rs.	Cwt.	Rs.
Shell-lac ..	193,305	2,58,93,713	217,593	2,64,53,774	205,473	2,89,75,551
Button-lac ..	34,276	38,70,479	41,851	44,41,287	37,117	44,45,914
Total ..	227,581	2,97,64,192	259,444	3,08,95,061	242,590	3,34,21,465
Stick- and Seed-lac ..	11,152	9,41,104	11,004	7,79,613	15,188	12,86,242
Grand Total of Foreign Exports ..	238,733	3,07,05,296	270,448	3,16,74,674	257,778	3,47,07,707

It will thus be seen that during the years 1903-6 the exports of shell-lac have increased by 12·56 per cent. in quantity and by 21·63 per cent. in value, while button-lac has correspondingly expanded by 22·1 per cent. in quantity and 14·75 per cent. in value. On the other hand, the traffic in the raw material has, if anything, declined. Everything points to a continued expansion of the traffic in connection with the necessities of electric appliances.

TA ARIN U INDICA, *Linn.*; *Fl. Br. Ind.*, ii., 273; Gamble, *Man. Ind. Timbs.*, 1902, 278-9; Prain, *Beng. Plants*, 1903, i., 444; Brandis, *Ind. Trees*, 1906, 252-3; Hooper, *Agri. Ledg.*, 1907, No. 2; **LEGUMINOSÆ**. The Tamarind Tree, *amli, tintiri, tintul, koya, pūli, chinta, jojo, chinch, neddi, shenta, sitta, karangi, hunase, magyi*, etc. A large evergreen tree, cultivated in India and Burma as far north as the Jhelum, in the Central Provinces, Central India, and many parts of Southern India; it is also found self-sown in waste and forest lands. Is said to be indigenous in Africa. According to Dutt, it was known to the Arabs as *Tamare-Hindi*, from which is derived Tamarind.

Qualities. Firminger (*Man. Gard. Ind.* (ed. Cameron), 254-5) speaks of three sorts—(1) the sour-fruited, (2) the sweetish fruited, and (3) the red-fruited. The last-named has the pulp of a rose-red colour and is considered the best, being the kind always employed, when obtainable, for preserving. It flowers in April and May, and yields its fruit in the cold season. The Natives have an aversion to sleeping under its shade because of the supposed acid exhalation from the leaves. On this subject, Gamble writes me: "I can testify that the leaves of the tamarind corrode the cloth of tents pitched under their shade. This happens in wet weather. The leaves fall on the tents, and in a day or two the cloth is decomposed in holes." Regarding cultivation, Woodrow says: "This tree delights in a deep alluvial soil, and in such a position forms one of the most handsome landscape trees in this country; but it will also grow on decayed trap soils where few trees will thrive without free watering. For planting get a hole at least 3 feet deep and 3 feet wide prepared, fill to 6 inches above the surface with good soil mixed with some old manure. Let the surface be raised at the sides, so to prevent water running off, and sow a few seeds at the beginning of the rains, then protect them with some thorny branches, which should be afterwards removed, the surface stirred, and the thorny branches replaced once in three months."

Gum. **Properties and Uses.**—It yields a dirty GUM of no value, and according to Prebble, old trees are sometimes seen to have a liquid exudation consisting of calcium oxalate (*Pharmacog. Ind.*, i., 533; Kanny Lall Dey, *Indig. Drugs, Ind.*, 1896, 310). An infusion of the leaves is believed to yield a red DYE and to impart a yellow shade to cloth previously dyed with indigo (Atkinson). Leaves, flowers and fruits are also employed as auxiliaries in dyeing, especially with safflower. An OIL of an

PREPARATION OF TAMARINDS

TA A T

U II

Chaulmu ra

amber colour is prepared from the seeds by expression. From a very remote period the tree has been valued in Sanskrit MEDICINE as an antiscorbutic in place of limejuice, and accordingly the fruit is officinal in modern Pharmacopœias. The fruit is a large swollen pod, 4 to 6 inches long, filled with an acid pulp. It matures in February and is largely used as Food, being a favourite ingredient in curries and chutnies, and for pickling fish (see Fish, p. 547). It is also employed in making a cooling drink or sherbet. According to Lakshman Dhargal Ker (*Therap. of Indig. Veg. Drugs, Bombay*, 1899, 16, 36, 88), the sherbet is a useful laxative for children. Marco Polo (ed. Yule, ii., 328) mentions *tamarindi* and seawater being used as an emetic preparation.

According to a recent writer (*Philippine Bureau of Agri., Press Bull., No. 6: Trop. Agrist., Nov. 1905, xxv., 687-8*), "In British India the average annual yield from an adult tree is 350 pounds of pods, and this shrinks to about 200 pounds of the prepared fruit pulp." The same writer states that a new market has recently sprung up for the tamarind in Genoa, where the pulp is employed in the manufacture of syrups and sweetmeats. The East Indian tamarinds, he says, are packed in salt, but the best market now seems to be for the unsalted article, of the preservation of which in Jamaica he gives the following account:—"After gathering, the ripe pods are first stripped of their outer shells and the pulpy contents are laid down in the bottom of wooden casks or barrels, and there sprinkled over with a layer of cheap, low-grade sugar. Then follow alternate layers of fruit and sugar, until the receptacle is filled to within 8 to 10 centimetres. The whole is now covered with boiling-hot sugar, headed up, and is then ready for export. So packed, tamarinds may be preserved for years without deterioration." He also adds, "The current price of salted tamarind in the Bombay market is at this time only about \$30 per long ton of Madras fruit and \$40 for Calcutta fruit, while the prevailing average price for the sweetened Jamaica fruit in the Genoa market for nearly a year past has been about 40 liras per 100 kilos (220 pounds) or, in our values, about \$80 gold per long ton."

The seeds, boiled or fried after removal of the outer skin, are also eaten by Natives, especially in times of scarcity, while the seedlings, leaves and even flowers, are utilised as food in various preparations. Cameron mentions a cement or paste as made from the seeds which is used in dressing country-made blankets. The WOOD is regarded as very durable, and is highly prized, though difficult to work. It is used chiefly for wheels, mallets, planes, furniture, rice-pounders, oil and sugar mills, and is excellent for turnery. It is also valued for fuel when great heat is necessary. [*Cf. Baber, Memoirs, 1519 (Leyden and Erskine, transl.), 1826, 341; Mesua, Opera (ed. Marinus), 1562, 52; Garcia de Orta, 1563, Coll., liii.; also in Ball, Proc. Roy. Ir. TA AKT G KU II, King, in Journ. As. Soc. Beng., 1890, lix., pt. 2, 121-4; Gamble, Man. Ind. Timbs., 42; Prain, Beng. Plants, 1903, i., 231-2; Hooper, Agri. Ledg., 1905, No. 5; also Rept. Labor. Ind. Mus., 1905-6, 29-30; BIXINEÆ. The Chaulmugra Oil, *chaulmugra, kalawabin* (the tree), *kalawithe* (the seeds), *taung pung*, etc. A large tree, 40 to 50 feet high, of the forests of Sylhet, Chittagong and Burma. The seeds yield the true *chaulmugra* oil, long supposed to be the product of *Gynocardia odorata*.

D. P.,
iv., 1 -5.
Chaul-
mu ra.

The identification of the true source of the *chaulmugra* seed originated with a

Confusion in the Seed. French pharmacist, G. Desprez. In 1899 he discovered that the seeds received in Europe did not belong to *Gynocardia odorata* and the fact was communicated to Lieut.-Col. D. Prain, who had found about the same time that the seeds sold in the Calcutta bazárs were not those of a *Gynocardia*, and subsequently that the tree which yields the *chaulmugra* seed was *Taraktogenos Kurzii*, a plant described by Sir George King in 1890. The two seeds can be easily distinguished. *Gynocardia* is about one-half shorter than that of *Taraktogenos*. The shell of *Gynocardia* is thicker and harder, marked on one side by a few radiating ridges or furrows, and the kernel is pale yellow. The shell of *Taraktogenos* is plain and the kernel dark-coloured.

Oil. *Chaulmugra* OIL has long been known and used in India as a remedy for cutaneous diseases, and has become a drug of some importance in European practice (p. 204). A full account of the history and composition of the oil is given by Hooper. The seeds are brought to Calcutta, chiefly from Chittagong, and are of two kinds—(1) mature seeds with brown kernels, rich in oil; (2) immature seeds with black kernels, poorer in oil. The seeds arrive in the market at the end of the rainy season in November and December. At present the price of the seed is stated to be Rs. 3 to Rs. 4 per maund at Chittagong and Sylhet, and the Calcutta price Rs. 6–9 per maund. To extract the oil the kernels are separated from the shells and dried in the sun. They are then pounded with a pestle and mortar, and the broken kernels put into canvas bags and the oil expressed with the aid of fire in a castor-oil mill. The oil is of two kinds—(1) clear, bright, straw-coloured; (2) muddy and precipitating a sediment of earthy colour. One maund of oil is obtained from 4 to 5 maunds of seed. The price of the oil is Rs. 60 per maund. [Cf. Mason, *Burma and Its People* (ed. Theobald), 1883, ii., 646; (*Gynocardia*) *Pharmacog. Ind.*, i., 142–6; Bories and Desprez, *Contrib. to Study of Gynocardee Chaulmoogra Oil*, 1898; Holmes, *Pharm. Soc. Mus. Plants*, ii., 828; Cooke, *Fl. Pres. Bomb.*, 1905, ii., 424; Brandis, *Ind. Trees*, 1906, 505–6; VERBENACEÆ. The Teak Tree, *ságún*, *sákhú*, *chingjagú*, *ság*, *síqwan*, *khaka*, *teka*, *loherú*, *ságwán*, *tégu*, *tékkú*, *pedda téku*, *tyagada mara*, *yádi*, *kyín*, etc. A large deciduous tree, indigenous in both peninsulas of India. The wood is that chiefly exported from India, more particularly Burma, and is the most important building timber of the country.

Areas. Indian. Gamble discusses the teak areas under two divisions, the western or Indian and the eastern or Burmese. "The Indian region has for its northern limit the rivers Nerbudda and Mahanadi, but here and there it may occasionally be found north of this line, as in Jhansi and Banda, while south of it, it scarcely occurs in Orissa or the Circars. It is found in deciduous forest, but is not gregarious; and the localities where the most important forests are found are (1) Chanda district, Central Provinces; (2) North Kanara; (3) Wynaad, especially the tracts known as Benné and Mudumalai; (4) the Anamalai hills; (5) Travancore. There are also considerable extents of teak forest in other parts of the Central Provinces; in Berar and Bombay; on both sides of the Godavari in Bhadrachalam, Rumpa and Yernagudem; in the Nallamalai hills of Kurnool and Cuddapah; in South Arcot and in Mysore. But teak may be found sporadically in places in forests throughout the Indian region, and even in such very dry apparently barren rocky hills as those of Western Karnúl and Bellary, patches of stunted more or less gregarious teak are not uncommon. In the Burmese region, teak is chiefly found in what are called by Kurz the 'upper mixed forests,' which occupy the parallel ranges of (1) the Arrakan Yoma, eastern slope; (2) the Pegu Yoma; and (3) the Martaban hills and the hills which continue these ranges northwards. The northern limit, according to J. W. Oliver, is about Myitkyina and Kamaing, in lat. 25° 30', though there it is mostly of stunted growth. Teak has been largely planted about stations all over India, even so far north as Saharanpur, Dehra Dún and Lahore, in avenues and gardens; and forest plantations have been made

in many provinces, the chief of which is that at Nilambúr in Malabar, commenced by Mr. Conolly, who was Collector in 1844. In Bengal it has been grown about Kaptai in Chittagong and Bamunpokri in the Darjeeling Terai; and in the Assam Valley there is a plantation as far up as Makúm near Dibrugarh."

Cultivation and Management.—The above paragraph gives a general idea of the distribution of teak throughout India and Burma. For further details regarding the distribution and general management of teak plantations the reader might consult the *Dictionary* (l.c. 5–10), where particulars will be found of climate, soil, cultivation, seed, nurseries, growth, felling and diseases. The voluminous *Forest Administration Reports and Working Plans* issued by the Imperial and Provincial Departments of India and Burma, as also the pages of the *Indian Forester*, are full of much important and practical information. [Cf. Brandis, *Teak Forests of Pegu*, 1856.] But the following are a few of the more important facts relative to the growth of the tree. It is said to thrive best with a mean average temperature of between 72° and 81°. Regarding the large plantation at Nilambúr in Malabar, Percy Lushington (*Rept. and Working Scheme of Nilambúr Teak Plantat.*, 1898, 41) states that "the distinguishing characteristic of the Nilambúr climate is its damp heat so favourable to rapid growth. The temperature in the shade ranges from 75° to 95°. The average rainfall for the past ten years is 94·5 inches." He then explains that the soil of the plantation is very varied, alluvium overlying gneiss rock or laterite derived from the hills. Gamble states that teak thrives best on sandstones and metamorphic rocks, but may also be found on trap, laterite and even limestone. At the Nilambúr plantation it has been recorded that the teak growing on alluvial soils was of first class; that on laterite second class. Damp alluvial soils are, however, unfavourable, and there must be good drainage if straight timber is to be obtained. The tree also requires full light for its head and free circulation of air. It seeds freely even when young, and the seed germinates well if it gets sufficient warmth and moisture. According to Gamble, "germination is best if the seeds are simply mixed with sand and dead leaves after being thoroughly soaked." J. W. Oliver says that in Burmese *taungyas* the practice is to spread the seed in a corner of the area chosen for the plantation, and then pick out and transplant to their proper places those which germinate. Gamble then continues, "as teak has an enormous tap-root, which resents being cut, the seedlings cannot be kept long in nursery, but must be planted out when quite small, and succeed best when planted out straight into the forest after germination," as has been mentioned above; "but when this is not feasible, basket or pot plants will give good results." McIntosh (*Ind. For.*, 1905, xxxi., 129) observes that at Nilambúr the seed is collected in February and sown early in April, after having been soaked for forty-eight hours in water. With copious waterings the seeds germinate in fifteen to twenty days. Regarding the management of natural teak forests, Oliver says that reproduction of teak is hardly satisfactory unless the forest is burnt, because, being usually mixed with bamboo, shade is too dense until the bamboo flowers, and then, unless the forest is burnt over, the bamboo seedlings choke such teak plants as may germinate. Gamble, summarising the *Working Plans*, says: "It has been ascertained by experience that great improvement takes place if certain well-defined operations are carried out, and these are usually prescribed. They are—(1) not to girdle isolated trees unless with the object of relieving existing seedlings; (2) to leave sound trees, likely to improve, in localities whence

THE TEAK-WOOD TREE

	large timber can be extracted ; (3) to fell and not girdle trees attacked by epiphytic <i>Ficus</i> ; (4) to continue <i>taungya</i> plantations with energy, and to weed such plantations regularly ; (5) to sow or plant up areas of flowered bamboo ; (6) to pay much attention to creeper-cutting." According to P. Lushington (<i>l.c.</i> 67-8), the method adopted in the Nilambúr plantation is "a system of high forest with a clean felling of the final crop and artificial regeneration. The felling to be accompanied by thinnings with a view to the improvement of the final crop. The felling to commence not earlier than the year in which the average girth at breast-height will be 6 feet 6 inches. The measurements taken show that the centre girth will not be less than 4 feet 6 inches. On first-class soil the final crop should consist of not less than forty trees, and on second-class of not less than fifty per acre." Lushington further states "the age of exploitability has been found out to be 95 years on first-class, and 140 years on second-class soils."
Trees to Acre.	
Age.	"The total yield per acre on first-class soils is 3,000 cubic feet per acre, and on second-class 2,000 cubic feet per acre. The annual yield, if spread over 50 years, will be 147,910 cubic feet of first-class and 73,780 cubic feet of second-class timber. According to the present market this will fetch not less than Rs. 3 per cubic foot standing for first class, and Rs. 2 per cubic foot for second class. The total revenue to be derived will, therefore, be Rs. 4,43,730 and 1,47,560 = Rs. 5,91,290, or with the net profit derived from miscellaneous sources such as third-class bamboos, etc., may safely be fixed at 6 lakhs per annum."
Yield.	
Profit.	
Tar.	Minor Products. —A somewhat liquid, black tar may be prepared by destructive distillation of the wood ; this is used for medicinal purposes in South India and Burma. The leaves yield a dye, of which little is known, and are employed as food for the <i>tasar</i> silkworm (<i>p.</i> 1005). An oil is also extracted from the wood, used in Burma as a medicine and as a substitute for linseed-oil in painting.
Dye.	
Oil.	
Wood.	Wood. —Teak owes its value chiefly to its great durability, ascribed to the fact that it contains a large quantity of fluid resinous matter, which fills up the pores and resists the action of water. As manifesting its durability, mention may be made of the fact that the great umbrella over the Htee in the Karli cave is still in existence, though it is most probably at least two thousand years old. Gamble observes that the weight may be taken at approximately 45 lb. per cubic foot and the value of P (the coefficient of transverse strength) at 600. When quite fresh teak hardly floats, but when seasoned it floats easily. The oil in the wood prevents its getting waterlogged, and seems also to safeguard it against weevil and other timber-boring insects. It is specially valued because it does not rust the iron with which worked up. It is exported chiefly for shipbuilding, especially for the decks of vessels, for the construction of railway carriages, and for the best class of house-carpentry, being admirably suited for stair-cases, balustrades, door and window frames and furniture. In India it is used for all purposes of house- and ship-building, for bridges, railway-sleepers, furniture, shingles, etc. It is used for carving, the Burmese carved teak-wood being especially noted ; in Burma itself carved "kyaungs," or monasteries, are prominent in almost every village of any importance (<i>Gamble, l.c.</i> 532). The ease with which teak-wood lends itself to carving has, in fact, originated special art conceptions ; these may be learned by perusal of the observations on this subject recorded in <i>Indian Art at Delhi in 1903</i> (100, 124, 129, 135-40).

Trade

the substitution of other woods to the permanent injury of the teak-wood trade (Hauxwell, in *Ind. For.*, 1905, xxxi., 618-35). No statistics are available of the Indian internal trade by rail and river, but the transactions by coast show that a large demand exists in India for teak-wood. This demand in former years was almost entirely supplied by Burma, but in recent years, as will be seen, one of the chief features of the present-day Indian trade in teak has been the gradual displacement of the Burmese timber, especially in the Bombay market, by wood imported from Siam and Java. Turning to the coasting trade, we find that for the five years 1900-1 to 1905-6, the registered imports averaged annually 116,639 cubic tons, valued at Rs. 93,38,559, and the registered exports 134,142 cubic tons, valued at Rs. 86,70,414. In the last year, 1905-6, the exports were 131,458 cubic tons, valued at Rs. 88,25,140. Of this BURMA exported 85,749 cubic tons (to Bengal, 47,578 ; to Madras, 24,253 ; to Bombay, 11,870) ; BOMBAY 44,084 cubic tons (to British ports within the province, 26,410 ; to Kathiawar, 9,599) ; MADRAS, 1,469 cubic tons (to Kathiawar, 654 ; to Bombay, 265 ; to British ports within the province, 195) ; BENGAL, 153 cubic tons (to British ports within the province, 113 ; to Madras, 39). Perhaps it may be said that an important feature of the Indian traffic in teak-wood is the imports brought across the land frontier. In 1899-1900 these were 73,912 tons, valued at Rs. 44,16,143, which came from Karen-ni (43,434 tons) and Zimme (19,067 tons). Five years later the imports were valued at Rs. 54,34,063—imported by the Salween. [*Cf. Dipl. and Cons. Repts.*, 1902, 6-11 ; 1903, 4-5.]

Burma Supply.

Siam and Java Supply.

Exports from
Burma.
From Bombay.

From Madras.
From Bengal.

With regard to the foreign trade, as already pointed out, the chief feature has been the rapid rise, within recent years, of a large import trade in teak from Siam, Java and the Straits. The figures of IMPORTS for the years 1901-2 to 1906-7 have been—1901-2, 17,842 cubic tons, valued at Rs. 13,03,968 ; 1902-3, 32,081 cubic tons, valued at Rs. 24,96,317 ; 1903-4, 34,588 cubic tons, valued at Rs. 30,55,695 ; 1904-5, 46,915 cubic tons, valued at Rs. 42,46,190 ; 1905-6, 71,676 cubic tons, valued at Rs. 62,17,331 ; and 1906-7, 61,696 cubic tons, valued at Rs. 60,71,557. Almost the whole quantity comes from Siam, whose exports to India during the years in question increased from 17,572 cubic tons in 1901-2 to 61,657 cubic tons in 1905-6, and in value from 12 to 53 lakhs of rupees. Three-fourths of these imports go to Bombay and the remainder chiefly to Bengal. Turning, by way of comparison, to the latest figures of the coasting trade, we learn that in 1905-6 Burma consigned to Bombay 11,870 cubic tons, while the supply of foreign teak, almost entirely Siamese, in that year amounted to 53,253 cubic tons. Noël-Paton points out (*Rev. Trade Ind.*, 1905-6, 44) that “practically the whole of the teak trade in the north of Siam is controlled by British Companies.” [*Cf. Siam Trade, Ind. For.*, 1905, xxxi., 464-71.]

Foreign Imports.

Siam

British Companies.

The EXPORTS from India during a similar period have been—1901-2, 60,671 cubic tons, valued at Rs. 71,53,855 ; 1902-3, 57,500 cubic tons, valued at Rs. 68,67,879 ; 1903-4, 73,913 cubic tons, valued at Rs. 91,45,605 ; 1904-5, 46,912 cubic tons, valued at Rs. 60,05,383 ; 1905-6, 52,78 cubic tons, valued at Rs. 70,41,660 ; and in 1906-7, 44,202 cubic tons, valued at Rs. 61,48,291. Four-fifths of the total go from Burma, amounting to 41,469 cubic tons in 1906-7, the surplus from Madras, Bo bay and Bengal. The great bulk of the exports is consigned to the United Kingdom, which in the last year took 30,318 cubic tons,

Bur

United Kingdom.

while the other chief markets are ordinarily Germany, Ceylon and Australia.

Price.

Commenting on the price of teak, Noël-Paton states: "A great expansion in shipbuilding and in some other branches of construction in the United Kingdom, Germany, and the United States, has synchronised with a contraction in the available supplies of teak, and has induced a rise of price—in some cases prohibitive. The average price in 1904-5 at Calcutta was Rs. 111 to Rs. 116 per ton of 50 cubic feet. In 1905-6 it was Rs. 120 to Rs. 125. Exports of teak have increased in quantity by 12·5 per cent. to 53,000 cubic tons, and in value by 17·25 per cent. to Rs. 70·4 lakhs. But the difference between these two percentage rates of increase does not gauge the enhancement in average value of a uniform quality of timber, for it is understood that a good deal of inferior wood has gone forward in the twelve months under report. Exports from Burma to India proper decreased by a further 5·9 per cent. and reached a value of only Rs. 71,30,683, while imports into India from Siam and Java increased by some 34·7 per cent. to a total of Rs. 57 lakhs."

Increase.

Plain*, 1903, i., 335-7; Brandis, *Ind. Trees*, 1906, 307-12; COMBRETACEÆ. A genus containing many species distributed over the tropics of the world. There are some 16 representatives in India, many being large trees, valued for their timber and as producers of the tanning fruits—Myrobalans. An interesting historic sketch of the knowledge of myrobalans will be found in *Hobson-Jobson* (ed. Crooke, 1903, 607-10).

Arjan.

T. Arjuna, Bedd. The arjan, kahu, gara-hatana, kanha, mangi, san-madat, vellai-maruda, tandra, tella-maddi, toukkyan, etc. A large deciduous tree on "banks of rivers and streams throughout Central and South India, extending as far north as Oudh. Beyond that, towards the north-west and in the Panjáb, it is found only as a cultivated tree; Burma; low country of Ceylon" (Gamble).

Gum.

Dye.

Wood.

It yields a clear transparent GUM met with in the bazárs of Northern India as a drug. The astringent bark is sometimes used as a DYE and TAN, and also in Native MEDICINE. The WOOD is apt to split in seasoning and is not easy to work, but is used for carts, agricultural implements, boats and for building. At the Mysore gold mines it is used for supports and is called "White Matti." The ash from burning the wood contains a very high percentage of lime (*Trop. Agrist.*, 1906, xxv., 870-1). [Cf. *Pharmacog. Ind.*, ii., 11-2; Cameron, *For. Trees of Mysore and Coorg*, 1894, 135-6; Duncan, *Monog. Dyes and Dyeing in Assam*, 1896, 52; Dutt, *Mat. Med. Hind.*, 1900, 163-4; Hooper, in *Agri. Ledg.*, 1902, No. 1, 38; Chandra, *Monog. Tanning and Working in Leather, Beng.*, 1904, 7; Trench, *Monog. Tanning and Working in Leather, C. Prov.*, 1904, 7.]

eleric.

T. belerica, Roxb. Beleric Myrobalan, bhairá, sagoná, lupúng, hulluvh, yehala, yella, tare, tani, tandi, kattu, elupav, santi, thitseim, etc. A large deciduous

USEFUL TANNING MATERIALS

T ALIA
ULA
Chebulic

tree, throughout the forests of India, Burma and Ceylon, below 3,000 feet ; absent from the dry countries of Sind and Rajputana.

This yields copiously a GUM which is insoluble in water. The fruit is exported from India under the name *beleric myrobalans*, and is employed in India as an inferior dyeing and tanning material. It has various MEDICINAL qualities ascribed to it, and the oil expressed from the seeds is used by the Natives. The kernels are eaten. If taken in excess, however, they are said to produce intoxication. The fruit itself is eaten when fresh by goats, sheep, cattle and monkeys. The WOOD is of little value, but is employed for planking, packing-cases, canoes, carts and plough shafts, and in the United Provinces for house-building. [Cf. Milburn, *Or. Comm.*, 1813, ii., 218; *Pharmacog. Ind.*, ii., 5-11; iii., app., 154; Cameron, *l.c.* 133-4; *Ind. For.*, 1900, xxvi., 280; Dutt, *l.c.* 162-3; Hooper, in *Agri. Ledg.*, *l.c.* 38.]

T. Catappa, Linn. The Indian Almond, *jangli-baddam*, *hindî-bâdâm*, *nat-vadom*, *vedam*, *tari*, *katappa*, etc. A large deciduous tree of the beach forests of the Andaman Islands; cultivated in most parts of India and Burma, especially near the coast.

It yields a GUM and, as with most other species of the *Terminalia*, the bark and leaves are astringent and contain tannin. The kernels yield a valuable OIL, very similar to almond-oil in flavour, odour and specific gravity. A writer in the *Indian Agriculturist* (April 1906) estimates the yield at 10 lb. of dry kernels per tree, and the oil by cold expression at 50 per cent. of the weight of kernels. This practically corresponds with the particulars given in the *Dictionary* as the experience of Mr. A. T. Smith of Jessore. Both kernels and oil are used MEDICINALLY, as are also the bark and young leaves. The kernels are largely eaten as dessert, and the oil-cake is considered a good FOOD for pigs. The tree is one of those on which the *tasar* silkworm is fed. [Cf. Cameron, *l.c.* 132-3; Hooper, *l.c.* 38-9; Woodrow, *Gard. in Ind.*, 1903, 313; Firminger, *Man. Gard. Ind.*, 1904, 241, 574; Cunningham, *Plagues and Pleasures of Life in Bengal*, 1907, 284, 302.]

T. tontosa, W. & A. The *saj* or *sag*, *sein*, *âsan* or *asain*, *piâsâl*, *hatana*, *atnal*, *amari*, *jhan*, *taksor*, *sahâju*, *maru*, *karkaya*, *sadri*, *ain*, *maddi* (or *matti*), *murada*, *toukkyan*, etc. A large deciduous tree, according to Gamble "perhaps the most widely distributed of all the important Indian trees."

It yields a copious transparent GUM, which exudes in large globular tears, said to be used as an incense and cosmetic, and to be eaten by the Santals. The bark is used occasionally as a DYE stuff and is MEDICINAL. Its chief use, however, is as a TAN, a property investigated recently at the Imperial Institute, the report of which was submitted by Dunstan to the Under-Secretary of State for India on Oct. 7, 1904, and though apparently not published it may be here remarked that the result of the analyses conducted showed that the bark of this plant contained a fair quantity of tannin, and the ratio of this to the total extractive matter present indicated that it should be possible to prepare from it an extract rich in tannin. In summing up, Dunstan states that the results indicate that it would be quite possible to prepare from the bark extracts which would furnish leathers of good texture and colour. The fruit is also used in tanning, but is very inferior to either the chebulic or *beleric myrobalans*. The WOOD is largely employed for house-building, carts, rice-pounders, ship- and boat-building, and is an excellent fuel. At the Mysore gold-mines this is called "Black Matti." Lac occasionally collected from its branches, and in some districts, such as Singhbhum in Chota Nagpur, the *tasar* silkworm is fed on the leaves. [Cf. Cameron, *l.c.* 136-8; Hooper, *l.c.* 41-2; Leete, in *Ind. For.*, 1900, xxvi., 239; Eardley-Wilmot, in *Ind. For.*, *l.c.* 377-8; *For. Admin. Repts.*]

T. Cheb 1, Retz. The Chebulic or Black Myrobalan, *harrâ* or *hâr*, *hikikha*, *silim*, *karedha*, *halra*, *rola*, *mahoka*, *kadakai*, *karaka*, *hîrada*, *alalê*, *panga*, etc. A very variable deciduous tree, found throughout India and Burma. The *Flora of British India* enumerates six varieties. "In high-level rocky and dry places on the outer Himalaya, the hills of the Deccan and South India, it is only quite a small tree, but in valleys and forests of big trees it also grows big and gives a hard, dark-coloured timber" (Gamble).

istory.—The tree yields a GUM, said to be largely collected in Berar and mixed with various other gums (*Acacia arabica*, *Anogeissus latifolia*,

	<p><i>Bassia longifolia</i>, etc.). The mixed gums are taken to the local markets by the Gonds, who collect them, and are sold for medicinal purposes or to dyers to mix with their colours. The chebulic myrobalan was highly extolled by the ancient Hindus as a powerful alterative and tonic. Indian writers describe seven varieties, which, however, are mostly the same fruit in different stages of maturity. The classic citrine myrobalan, of which Rhases, Serapion, Avicenna, Mesua, etc., all speak favourably, was at one time much in demand in Europe. Even so late as 1813, Milburn (<i>l.c.</i> 218) gives directions for selecting the drug, which, he adds, the Natives frequently candy. Fleming (<i>As. Res.</i>, 1810, xi., 182) ascertained the <i>zengi har</i> (black myrobalan) to be the unripe fruit of this species (Sprengel, <i>Hist. rei. Herb.</i>, 1808, i., 262; <i>Paulus Ægineta</i> (Adams, Comment.), iii., 440-3). The Wood takes a good polish, is fairly durable and used for furniture, carts, agricultural implements and house-building.</p>
Wood.	
Myrobalans.	<p>Dye and Tan.—The dried fruit of this species constitutes the “Chebulic” and “Black” myrobalan of commerce, one of the most valuable of Indian tanning materials. In India it is also used as a dye occasionally by itself, the rind of the fruit being powdered and steeped in water. With alum it is said to give a good permanent yellow. But the most extensive use to which <i>harra</i> is put as a dye is in the production of various shades of black, in combination with some salt of iron. The chief commercial value, however, of chebulic myrobalan is as a tanning material; it forms the greater part of the ground myrobalans of commerce, though beleric myrobalans are occasionally mixed with it. The liquor prepared from <i>harra</i> is not only a powerful tan, but imparts a bright colour to the leather, and hence is highly esteemed for mixing with other tanning agents.</p>
Dye.	
Tan.	
Chemical Nature.	<p>“The tannins in myrobalans appear to consist almost entirely of pyrogallol tannins, gallotannic acid being present; consequently the material blooms well. It gives a greenish-yellow colour to the leather and a porous tannage, so that it is not used alone but may be advantageously employed with materials such as hemlock, which yield a dark colour; it is much used with oak bark and valonia” (Blount and Bloxam, <i>Chem. for Engin. and Manuf.</i>, ii., 377). Considerable difference exists in the proportion of tannin contained in the fruits. Specimens supplied from Madras, Bombay, Bengal and the United Provinces furnished percentages of tannin ranging from 13 to 38. It has also been shown that the fruit exhibits two well-recognised forms. The best qualities are known in trade to be oval and pointed, and of a pale greenish-yellow colour in section, solid in structure. The less valuable qualities are round and spongy. It has been ascertained that the oval form is simply a less mature condition. Some interesting facts regarding the commercial value of various samples of myrobalans are given by a writer in <i>Capital</i> (Jan. 7, 1904). [<i>Cf. Ind. For.</i>, xxx., 188-91.] “In English,” it is stated, “there are five chief varieties of myrobalans, called after the districts in India from which they are obtained. These are (1) ‘Bhimlies,’ from Bimlipatam in Madras; (2) ‘Rajpores’; (3) ‘Jubbelpores,’ from Jabbalpur in the Central Provinces; (4) ‘Vingorlas’ from the Bombay forests; and (5) ‘Madras Coast.’ The price and quality of these nuts vary exceedingly, whilst the opinion as to their actual value in the tanning trade is widely conflicting. Some tanners maintain that Jubbelpore myrobalans, or J’s, as they are technically called, are worth more than Bhimlies or B’s; while others are equally strong in their preference for B’s in comparison with J’s. Some tanners prefer the</p>
Round and Oval.	
Trade Names.	

light-green coloured nuts, which are higher priced than the others, while some like the dark or browner kind. One remarkable instance is recorded of a tanner who rejected a delivery as being darker in colour than the sample, and on arbitration secured an allowance of £1 per ton. It was afterwards found that the myrobalans were 3 per cent. stronger in tannin than the original sample, which in the opinion of the arbitrators was worth £1 a ton more than the delivered bulk. Some tanners buy myrobalans for their strength and cheapness, when compared with the price of oak bark and valonia, others use them on account of their brightening colour, while others use them because of the light-coloured bloom they deposit on leather." Colour.

In the *Journal of the Society of Chemical Industry* (1903, xxii., 1181-4, 1338) will be found an interesting paper by Dr. J. Gordon Parker and Mr. F. A. Blockley on the relative tanning values of different species and growths of myrobalans. The authors discuss (1) the content of tannic acid in various samples, (2) extent of bloom, (3) acidity, and (4) price of unit of tan in the samples examined. The tannic content was found to vary from 27.3 per cent. in a sample of Jabbalpur, to 38.4 in a sample of Bhimley. With regard to bloom, it was found that Jabbalpur and Vingorla myrobalans were much superior to other sorts, both in the amount yielded and the readiness with which their solutions deposited the same, while with regard to acidity, the Bhimley variety developed most and the Jabbalpur least. The value of the unit of tan per ton was found to be 4s. 3½d. in the most expensive variety (picked Bhimley), and 2s. 2½d. in the cheapest (Bhimley 2). Tanning Values.

Trade.—*Internal.*—The *Report of Forest Administration* issued annually by the Inspector-General gives the exports from the forests under his control. The average for the five years ending 1902-3 came to 1,022,540 cwt., and for 1903-4 they were 1,299,600 cwt., valued at Rs. 42,10,288, or an increase of 4½ lakhs on the value of the preceding year. The internal transactions in myrobalans as registered by rail and riverborne traffic amounted in 1905-6 to 1,080,094 cwt., and in 1906-7 to 869,427 cwt. The chief exporting centres are the Central Provinces and Berar, Bombay, Rajputana and Central India, Bengal and Madras; the chief importing towns are Bombay, Calcutta, the Madras ports, and the importing provinces the United Provinces, and Bengal. Similarly the exports by coast in 1905-6 amounted to 218,146 cwt., valued at Rs. 4,62,454. Practically the whole of this export trade goes from Bombay to British ports within the province. Trade.

External.—The foreign trade is large and important. During the period 1900-7 the following quantities have been exported:—1900-1, 945,648 cwt., valued at Rs. 31,68,173; 1901-2, 1,085,174 cwt., valued at Rs. 35,63,652; 1902-3, 1,157,650 cwt., valued at Rs. 37,72,255; 1903-4, 1,229,609 cwt., valued at Rs. 42,10,288; 1904-5, 1,187,585 cwt., valued at Rs. 42,59,063; 1905-6, 1,206,398 cwt., valued at Rs. 44,60,676; and in 1906-7, 1,162,219 cwt., valued at Rs. 43,97,591. Analysing the figures of the last year, we find that of the total, Bombay exported 748,279 cwt., Bengal 292,816 cwt., Madras 121,123 cwt., while the chief markets, with the quantities received by each from India, were, in order of importance, the United Kingdom, 581,481 cwt.; Belgium, 200,729 cwt.; Germany, 191,669 cwt.; Austria-Hungary, 67,476 cwt.; and France, 46,304 cwt. Exporting Centres.

Cacao.

THE ROMA CACAO, Linn.; Hayne, *Gewächse*, 1825, ix., 35; Bentley and Trimen, *Med. Pl.*, 1880, i., 38; Köhler, *Med. Pflanzen*, ii., 157, tt. a and b; Morris, *Cacao, How to Grow and How to Cure It*, 1882, 1887; Hart, *A Treatise on Cult. and Curing, etc.*, 1892; Lecomte et Chalot, *Le Cacaoyer et sa Cult.*, 1897; Gamble, *Man. Ind. Timbs.*, 93; Brandis, *Ind. Trees*, 79; STERCULIACEÆ. The Cacao (sometimes also written Cocoa) and Chocolate. A small tree indigenous to Central and South America, now largely cultivated in many moist tropical countries.

Oil.

Oil or Butter.—A light-yellowish opaque, solid oil, known as "Cacao Butter," is expressed from the warmed seeds. This has the pleasant odour of chocolate, melts in the mouth with a bland, agreeable taste, has a specific gravity of 0.961, and fuses at 20° to 30° C. Recently a large trade has been organised in the less expensive solid oil or butter prepared from COCOANUT OIL (see p. 359-60), which has unfortunately also come to be sometimes described as "Cocoa Butter."

Nibs and
Chocolate.

Cacao Nibs and Chocolate.—The chief product of this plant is the CACAO BEANS or NIBS—the specially prepared seeds—from which Chocolate is manufactured. The tree is raised from seed, is grown at distances of 15 to 20 feet apart, comes into full bearing in the fifth to seventh year, and fruits for a number of years subsequently. The flowers, which are very small, are formed on the naked stems and older branches; the fruits become 6 to 9 inches long, and each contains 40 or more large seeds—the beans or nibs of commerce. A tree will yield from 1 to 10 lb. dry nibs in the year, according to climate, soil, and treatment to which the plant has been subjected. The seeds are removed from the pods, conveyed to the fermenting-house, and subjected to a process of "sweating" for three days. They are then examined, their positions changed, and repacked for a further fermentation of three days. Next comes the process of rubbing or washing to free them from dirt and the ruptured seed-coats, lastly the drying or "curing." To accomplish the final treatment, they are subjected to the sun, the while being protected from rain or dew, and the term of exposure extended each succeeding day until they are quite dry; but a too rapid drying is regarded as injurious. The nibs are now ready and are in consequence packed and dispatched. In the production of chocolate the nibs are usually roasted, ground to a fine powder and flavoured with sugar, vanilla, etc., etc. In estimating for trade purposes the various confectionery, the proportion of chocolate they contain is stated, as also the amount of alcohol present, if any. A singular feature of this branch of the trade is the very large quantity procured from Belgium (404,844 lb., valued at £36,818 in 1906).

Trade.

TRADE.—The tree has been repeatedly introduced into India (*Kew Rept.*, 1873, 7; 1881, 28). It is grown to some extent in Malabar, the Nilgiri hills, etc., but not with the success attained in Ceylon; there seems, however, no good reason why this should be so. The imports of "Raw Cocoa" mentioned in the

TINSTONE OF INDIA AND BURMA

returns of Great Britain have ranged from 50 to 60 million pounds during the five years ending 1906, and these quantities have been returned at approximately 1½ million pounds sterling in value. The traffic in Chocolate is much smaller in quantity, but of course relatively much more valuable, namely from 8½ to 10½ million pounds in weight and close on one million pounds sterling in value. In addition to these supplies of chocolate, there is the traffic in confectionery to which reference has already been made. The trade in cocoa butter is still smaller, but, as already mentioned, some proportion of the published returns of that substance must denote cocoanut "Cocoa Butter" and not "Cacao Butter." Of the imports of Raw Nibs, the British West Indies (especially Trinidad and Granada) head the list of supplying countries (17 million pounds on the average of the five years named); then come Portugal with 14 million (re-exporting, no doubt); Ceylon with 4½; France with 4½; Ecuador with 4; Brazil with 3; and lastly, the British West African (Lagos) supply has expanded from 303,635 lb. in 1902 to 2,112,352 lb. in 1906. [*Cf. De Candolle, Orig. Cult. Plants*, 313; *Agri.-Hort. Soc. Ind. (Trans.)*, 1839, iii., 39; vi., 127; 1840, vii., 81; (*Proc.*) 1843, ii., 208, 397, 443, 591; (*Journ.*) 1845, iv., 140; (*Proc.*) 1854, viii., 48; (*Journ.*) 1857, ix., 292; 1869, i., 83; (*Corresp. and Select.*) 1882, vi., 71; (*Proc.*) 31; (*Journ.*) 1886, vii., 20; (*Corresp. and Select.*) 29-40, etc.; *Ceylon Cacao, Kew Bull.*, 1890, 170; also *Honduras Cacao*, 1893, 327; and *Ecuador Cacao*, 1899, 42, etc.; *Cacao Indust. in Granada, West Ind. Bull.*, 1900, i., 415-22; also *Art. Drying of Cacao*, 1901, ii., 171-4.]

TIN.—Ball, *Man. Econ. Geol. Ind.*, iii., 313; Hughes, *Tin Mining in Mergui*, in *Rec. Geol. Surv. Ind.*, 1889, xxii., pt. 3, 188-208; Holland, *Rev. Min. Prod. Ind.*, 1898-1903, in *Rec. Geol. Surv. Ind.*, 1905, xxxii., pt. 1, 90-3; 1907, xxxvi., pt. ii., 81. Tin is said rarely to occur native or as the sulphide (stannite). The commercial ore is known as the dentoxide, cassiterite, or "tinstone." When pure this contains about 78 per cent. of the metal.

D.E.P.,
vi., pt. iv.,
57-62.
Tin.

Occurrence.—Within India proper tinstone may be said to be but rarely found, but in Burma, more especially the southern portion of Tenasserim, it forms extensive and valuable deposits. According to Holland (*l.c.* 1905, 90-1), however, "tin has a wider distribution than is generally recognised, and its minerals are often overlooked through the difficulty in distinguishing them from other heavy minerals. Isolated crystals of cassiterite have been found recently in pegmatites associated with gadolinite in the Palanpur State, whilst in the Hazaribagh district of Chota Nagpur instances have been recorded of the accidental production of tin from river-sands by the Native iron-smelters, in addition to the recorded occurrences of ores *in situ*. The principal deposit, which has either been wrongly described or has received less attention than it deserves, occurs in the Palganj estate near the Barakar river.

Occur-
rence.

"The only persistent attempts made to work tin have been in Burma, where cassiterite is obtained by washing river gravels in the Bawlake State, Karen-ni, Southern Shan States, and in the Tavoy and Mergui districts of South Burma. The work done on these deposits hitherto has been, however, on a smaller scale than might be expected from the favourable reports which have been made as to their extent and richness."

ur a
supply.

He further states that the average outturn of tin-ore in South Burma, during the period reviewed (1898-1903), was 1,645 cwt., valued at £6,876, and in 1906, 1,919 cwt., valued at £13,574. "The metal is exported mainly, in the form of block tin, almost all of it going to the Straits Settlements. This, during the years 1897-8 to 1902-3, averaged 661 cwt. a year." During the same period, Holland points out that the average consumption of foreign block tin in India itself was 24,959 cwt.; "the tin exported from

Exports.

Burma is a small quantity compared to the requirements of the country." The average daily attendance at the tin mines in the Mergui and Tavoy districts was 145 persons in 1905 and 141 in 1906.

Uses.

Mordant in Dyeing.

Kalaied or Tinned vessels.

USES.—A salt of tin is a highly important material in certain methods of dyeing, as practised in Europe, but in this respect it is apparently unknown to the Natives of India. It has, however, been used from a very remote period in Native medicine. [*Cf. Dutt, Mat. Med. Hind.*, 1900, 69-71.] By certain classes, especially the Muhammadans, the metal is also extensively employed in tinning copper vessels. Copper vessels, to be free from poisonous deposits, must be tinned or *kalaied* once a month, thus affording constant employment to a large number of workmen, known as *gal'aigars* or *kalaigars*, who are Muhammadans. In Northern India, vessels which are tinned for the first time are boiled in a solution of alum, verdigris, sulphate of copper and sal ammoniac. On subsequent occasions they are simply coated with tin without any previous preparation save that of removing the old *kalai* by scrubbing the vessel with ground *kankar* (brick dust). Tin, reduced to powder, is mixed with sal-ammoniac and applied by means of a piece of cotton, the vessel being heated on a charcoal fire. It is then polished with sand and ashes.

Artistic Appliances.

United Kingdom.

Exports.

Artistic manufactures, in which tinning forms a definite feature, assume importance in several centres. Of these the most noted are Moradabad, Jaipur, Peshawar and Kashmir. The art seems to have come from Persia, and is essentially Muhammadan in origin (*Ind. Art. at Delhi*, 1903, 16). Tin metal is also beaten into leaf or tin foil, and, after being coloured with lac, is sold in that condition and largely employed in the manufacture of cheap jewellery, tinsel decorations, and as an adjunct in ornamental turnery. Powdered tin foil may also be mixed with lac to produce a metallic effect. Still another use to which the metal is put may be mentioned, namely the preparation of certain alloys, such as that of Bidri ware (*Ind. Art., l.c.* 46, 211, 217-8).

Trade.—Although the uses of tin are both varied and widespread, relative to other items of trade the metal may be spoken of as comparatively unimportant. And as already indicated, the supply consists chiefly of that obtained from foreign countries. Imports for the period 1900-7 have been as follows:—1900-1, 22,741 cwt., valued at Rs. 22,08,560; 1901-2, 26,002 cwt., valued at Rs. 23,54,456; 1902-3, 28,000 cwt., valued at Rs. 25,58,162; 1903-4, 40,486 cwt., valued at Rs. 39,29,787; 1904-5, 39,323 cwt., valued at Rs. 39,36,023; 1905-6, 21,152 cwt., valued at Rs. 24,17,290; and 1906-7, 20,336 cwt., valued at Rs. 29,44,061. Analysing the figures for the last year, we find that 19,967 cwt. consisted of UNWROUGHT (block) tin and 369 cwt. of WROUGHT tin. Of the total imports, Bengal takes roughly one-half, 10,864 cwt. in 1906-7, the balance being divided between Bombay, Burma and Madras. Of the unwrought tin, practically the whole quantity comes from the Straits, viz., in 1906-7, 17,486 cwt., and the balance chiefly from the United Kingdom. It should be noted, however, that a considerable shrinkage occurred in 1905-6, the imports from the Straits having declined by almost a half, and the total imports from 39,323 cwt. (in 1904-5) to 21,152 cwt.

It has already been mentioned that the exports go entirely from Burma, and consist mainly of block tin. During the period reviewed by Holland (1897-8 to 1902-3), these averaged 661 cwt. Since then the figures have been:—1903-4, 480 cwt., valued at Rs. 38,829; 1904-5, 457 cwt., valued at Rs. 38,268; 1905-6, 426 cwt., valued at Rs. 36,761; and 1906-7, 929 cwt., valued at Rs. 72,312. They have thus been increasing. Practically the whole of the exports are consigned to the Straits. Small quantities of foreign tin are also re-exported from India, chiefly from Bombay to Persia and Turkey-in-Asia. The averages during the six years 1900-6 came to 1,500 cwt.; the actual in 1905-6 was 844 cwt., valued at Rs. 90,926.

Commenting on the production, consumption and prices of tin for the

year 1905-6 throughout the world, Noël-Paton (*Rev. Trade Ind.*, 12-3) affords many interesting particulars that will repay perusal.

The Hawk-bill Turtle or Indian Caret, *kachakra*, *alungu-thadu*, *ammah*, *sisik-kurakura*, *sisik-panu*, etc. Is a marine carnivorous species, plentiful on the coasts of Ceylon and the Maldives.

Hawk-bill
Turtle.

The Natives eat the flesh but it is unpalatable to Europeans, though the eggs are regarded as equal to those of other turtles. One of the errors of commerce is to speak of "tortoise-shell": the name should rather be "turtle-shell"; and though other species afford shells sometimes used as substitutes, this animal affords the true tortoise-shell. Its value depends on a warm translucent yellow colour, dashed and spotted with rich brown tints, and on the high polish which it may take. In China, shells with white ground and black spots that touch each other are most admired. The finest shell is obtained from the Western Archipelago, but is exported from the southern coast of the Indian continent, Ceylon, the West India Islands, and Brazil. The scales are detached from the turtle either by actual force after the animal is killed or by immersion in boiling water. If taken from the animal that has died a natural death or after decomposition has set up, the shell becomes clouded and milky. From very earliest times tortoise-shell has been a prized ornamental material. It was brought from the East to ancient Rome by way of Egypt, and was used as a veneer for furniture. Vincent (*Periplus*, etc., 1800, app., 48) says that in the time of the *Periplus* this article was largely traded in, being procured from Africa, Socotra, Malabar, Laccadive and Maldivé Islands, etc. In modern times it has been employed in Europe for the characteristic inlaying work known as *Bhul Marquetry*. It is used as a veneer for small boxes and frames and moulded into snuff-boxes and cigar-cases, also formed into knife and razor handles or cut into combs. Vizagapatam may be said to be the chief Indian locality where tortoise-shell is utilised in ornamental work. [*Cf. Fryer, New Acc. E. C. y : Boulenger, *l.c.* 48.

The Green or Edible Turtle or the *leik-pyen-won* or *leik-kyae* of Burma. This is a herbivorous animal found in the tropical and sub-tropical seas, though rare in the Bay of Bengal. Its flesh forms an important title of food, though at certain seasons it is said to become poisonous. The turtle of the Indian seas is believed to rival in size and flavour that of the Atlantic. The eggs are very rich and have a taste somewhat like marrow; they may be kept for weeks even

The Singhára Nut, Water Chestnut, *singhára*, *paníphal*, *gaúnri*, *shingódá*, *kubyakam*, *karim-polam*, etc. A floating herb, found in lakes, tanks and pools throughout India and Ceylon; often specially cultivated for its edible fruit. [*Cf.* *Cyperus esculentus*, p. 465.]

Ain-i-Akbari.

This aquatic plant has been grown in India from the most ancient times. Ball suggests that it may be the edible fruit which Garcia de Orta describes under the name *das caceras* (1563, *Coll.*, xi.; also in *Proc. Roy. Ir. Acad.*, 3rd ser., 1889-91, i., 397), but that I am disposed to regard as a mistake. It is, however, mentioned in the *Ain-i-Akbari* (1590) as one of the crops on which revenue was levied (Jarrett, transl., 1891, ii., 65). In certain parts of the country the kernels are ground down and employed for making the coloured powder (*gulal*) used during the *Hólí* festival. The flour, moreover, is considered by the Natives a cooling and useful article of food in bilious affections and diarrhoea, and it is in addition employed in the preparation of poultices. Both the kernels and the flour made from them are largely used as food, and in all localities where the plant occurs in any quantity. In fact it may be said to be extensively cultivated, *e.g.* in Kashmir, the United and Central Provinces, etc. For this purpose the fruits or nuts are scattered over the water at the end of January and pressed into the mud. In a month they begin to throw out shoots, and in June the plants are thinned out and transplanted. The nut forms under water in October, and is gathered in November and December. A highly instructive account of *singhára* cultivation will be found in Sir Walter Lawrence's *Valley of Kashmir* (1895, 72-345, 354-5). He speaks of it as less cultivated now than formerly. Moorcroft (*Travels*, 1823, ii., 136, 227) estimated the production at 384,000 maunds of nuts a year, but in Lawrence's opinion the production to-day might be more safely returned at 100,000 maunds. He observes, "Of the chief varieties the best is called *basmati*, in honour of the rice of that name. The *basmati* is a small nut with a thin skin, and gives one-third of kernel for two-thirds of shell. The *dogru* is a larger nut with a thicker shell, and the *kangar* has a very thick shell with long projecting horns and gives the least kernel of all."

Seasons.

Production.

R .

Extended
Production.

A more extended cultivation of the *singhára* nut in all localities where water abounds has been advocated at various times, and experimental cultivation in the reservoirs and lakes of the Madras Presidency has been specially recommended. The kernel abounds in starch, and is eaten either raw or cooked, especially by Hindus. It may be boiled whole, after soaking a night in water, roughly broke up and made into a sort of porridge, or ground to meal and made into *chapattis* [*Cf.* *Paulus Ægineta* (Adams, Comment.), iii., 378; Jones, *As. Res.*, ii., 350-1; Forster, *Travels*, 1798, ii., 29; Sleeman, *Rambles of an Official*, 1844, i., 101; Fortune, *Tea Dist. of China*, 1853, ii., 11; *Journ. Agri.-Hort. Soc. bitaceous plants, several species of which are cultivated throughout India for use as vegetables.

T. anguina, Linn.; Duthie and Fuller, *Field and Garden Crops*, ii., 45, t. xlv. The Snake Gourd, *purwul*, *chichinga*, *jhajhinda*, *galar tori*, *pandol*, *rebhri*, *padval*, *linga potta*, etc. An annual creeper, considered by De Candolle to have been originally wild in India and the Indian Archipelago. It is cultivated throughout India as a rainy-season crop. The long cucumber-like fruit is eaten as a vegetable, either boiled or in curries. Gathered when very young and cut into strips, it is extensively cooked in the same way as French beans. [Cf. Woodrow, *Gard. in Ind.*, 1903, 330; Firminger, *Man. Gard. Ind.*, 1904, 172.] nake
Gourd.

T. cucu erina, Linn.; Kirtikar, in *Journ. Bomb. Nat. Hist. Soc.*, 1892, vii., 487-8, t. E. The *jangli-chi-chondá*, *banpatol*, *gwal kakri*, *rán parul*, *ráná-chapada-vali*, *káttup-pépudal*, *adavi-potta*, etc. A climbing annual, found throughout India and Ceylon. It has various medicinal qualities ascribed to it, and the tender shoots, dried capsules, seeds, leaves and roots are all used in Native medicine. The ripe fruit is said to be stewed and eaten by the Natives. [Cf. *Pharmacog. Ind.*, 1891, ii., 72-4.] Vegetable.

Medicine.

T. dioica, Roxb.; Duthie and Fuller, *l.c.* iii., 23. The *parvar*, *potól*, *kombu-pudalai*, *kommupotta*, *patolam*, etc. An extensive climber common throughout the plains of Northern India, from the Panjáb to Assam and Eastern Bengal.

It is extensively cultivated during the rains. In Bengal, cuttings are planted at the end of the rainy season and fruiting goes on from March to September, after which the crop may be kept for a second year by ploughing and weeding in October and irrigating in February and March. Mukerji estimates the cost of cultivation in Bengal at Rs. 26 per acre and the outturn at 100 maunds, worth about Rs. 60. The leaves, fresh juice, and the fruit and root are all used medicinally, while the unripe fruit is eaten by the Natives and the tender tops are cooked as a pot-herb. The young or unripe fruit is valued by Europeans, and next to potatoes and *brinjals* is perhaps the vegetable in greatest favour. [Cf. Banerjei, *Agri. Cuttack*, 1893, 117, 197; Dutt, *Mat. Med. Hind.*, 1900, 169-71; Mukerji, *Handbook Ind. Agri.*, 1901, 347-8; Firminger, *l.c.* 172; Roy, *Crops of Beng.*, 1906, 143-5]. Seasons.

vi., pt. iv.,
5-.

T. corniculata, Linn.; Roxb., *Fl. Ind.*, iii., 389; Hamilton, *Stat. Acc. Dinaj.*, 194. The *lunkaika*, *piring*. Cultivated as a pot-herb. Hamilton observes that it is as good as spinach and is cultivated in the same manner. Vegetable.

T. n - r eu, Linn.; Duthie and Fuller, *Field and Garden Crops*, iii., 46, t. xcix. The Fenugreek or Fenugræc, *méthi*, *haenugreeb*, *shamli*, *bhaji*, *vendayam*, *mentulu*, *ménthyá*, *uluva*, *pe-nán-ta-rzi*, etc. A robust annual herb, wild in Kashmir, the Panjáb and the Upper Gangetic Plain; cultivated in many parts, particularly in the higher regions. Fenu reek.

No estimate can be given of the area under the crop, except in Bombay (including Sind) and Berar, where, according to the *Season and Crop Reports*, it occupied 2,713 acres and 519 acres respectively during 1904-5. Subsequent areas do not appear to have been recorded. It is grown near wells and on *sailáb* lands. On well lands, it is generally sown after cotton or *judr*. The seed (30 lb. per acre) is sown in February and the crop is ready to cut in April. On *sailáb* lands it is sown at the end of Octob or beginning of November, and the crop ripens about the same time on well lands. The seeds yield a yellow DYE, and the plant has been known and valued a MEDICINE from remote antiquity. It is grown chiefly as a food and fodder crop, and as a perfume. [Cf. *Paulus Ægineta* (Adams, Comment.), 184., iii., 373-4; Serapion, *De Simpl.*, 1473, §171; Taleef Shereef, 1650 (Playfair, transl.), 1833; Area.

Indian Names.

WHEAT (*froment*, Fr.; *weizen*, Germ.) has numerous Indian synonyms. The grain would appear to be most widely known in Sanskrit by the name *godhuma*, and according to Dutt (*Mat. Med. Hind.*, 269), "three varieties of wheat are mentioned in the *Bhāvaprakāsa*, namely *mohāgodhuma* or large-grained, *madhuli* or small-grained, and *nihsuki* or beardless." The first, we are told, came from the West, and the second was indigenous to India. The most general vernacular names are often closely connected (like the Persian *gandum*) with the Sanskrit *godhuma*, thus:—*géhún* or *giún*, *gahu*, *ghum*, *gohum*, *gahung*, *ghavum*, *gawn*, *gom*, *gam*, *gih*, *kanak*, *kank*, *rozatt*, *dro*, *do*, *zud*, *gandum*, *godumai*, *gódu-mulu*, *godhi*, *kótanpam*, *gyonsaba*, etc., etc.

History.

istory.—The cultivation of wheat, says De Candolle, is prehistoric. It is older than the most ancient languages, each of which have independent and definite names for the grain, such as the Chinese *mai* and the Hebrew *chittah*, etc., in addition to the Sanskrit names already mentioned. The Chinese grew wheat 2700 B.C. Heer found a small-grained wheat in the deposits identified with the earliest lake-dwellers of West Switzerland—date about the time of the Trojan war or earlier. Unger detected the same grain in a brick of the pyramid of Dashur in Egypt, to which he assigned the date of 3359 B.C. Another form of wheat has been found in the less ancient deposits of the lake-dwellers of Switzerland and Italy (Stone Age), and still a third or intermediate form at Aggtelek in Hungary. According to Hackel, the wheat found in the most ancient of these deposits is *T. dicoccum*. This is a summer wheat grown occasionally in Southern Germany, Switzerland, Spain, Servia and Italy, and used largely in the manufacture of starch. The more recent forms, that author identifies as belonging to *T. monococcum*. Hitherto it has been affirmed that the wheats found in association with the lake dwellings were quite distinct from any known modern wheats, but Hackel's determinations would seem to remove that impression, while confirming the belief that the wheat named preceded the appearance of those which constitute the bread wheats of to-day.

Ancient
Records.

Summer
Wheat.

Mesopotamia.

On the authority of Berosus—a Chaldean priest—wild wheat is accepted as having been seen in Mesopotamia. But similarly, the evidence of Strabo (who lived 50 B.C.) is often given as supporting the belief that wild wheat had been discovered in the Indus valley. In another place (p. 823) I have produced evidence, however, in favour of the idea that the wild plant that looked like wheat—of which Strabo spoke—may have been *Oryza coarctata* and not wheat at all. Other early references to wild wheats might still be given, but their value may be questioned when it is added that no modern botanist has recorded the discovery of wild wheat, nor, in fact, given any very satisfactory evidence of feral wheats (that is to say, of wheats that had survived in a self-sown condition from former cultivation). The authentic cases of wild wheat recorded by modern travellers, far as can be ascertained, are unconnected with the true wheat

VARIETIES AND RACES

T ITICU
VUL A
istory

Modern wheat would appear to be a product of cultivation of which little trustworthy evidence exists as to its origin, except perhaps that it is more closely connected with Asia than with Europe.

A remarkable silence may be said to characterise the writings of European authors regarding wheat cultivation in India, until well into the 18th, if not the beginning of the 19th century. Perhaps the earliest references are found in the records of provisioning the ships which in 1607 sailed from England to the East. These were commanded by William Keeling and William Hawkins, the latter, on reaching Surat, having had instructions to proceed on a mission to the court of the Great Moghal. In the list of articles supplied to the Pinnace, we read of so many "bushells of Steale Wheate" (see p. 250). Sir George Birdwood, in a footnote to the above passage (*E.I.C. First Letter-Book*, 99), says that it was French wheat that the ships took on board, the word "Steale" being probably derived from the "steelynes and hardnes" which was supposed to be the peculiar property of the foreign-grown commodity, and to make it therefore more suitable for the manufacture of biscuits for long voyages. The passage may be accepted as suggestive of the early introduction from Europe of some of the forms of hard wheat presently grown in Western India, as for example the *speltis*. But if that be so, a very different story is given by Terry (*Voy. E. Ind.*, 1655 (ed. 1777), 87), who speaks of the wheat of Surat as "more full, and more white than ours, of which the inhabitants make such pure, well-relished bread, that I may say of it, as one sometimes spake of the bread made in the bishoprick of Leige, it is *panis pane melior*, bread better than bread." So also Fryer (*New Acc. E. Ind. and Pers.*, 1672-81, 119) mentions the Deccan as possessing "wheat as good as the world affords." It is, however, significant that Milburn (*Or. Comm.*, 1813) makes not the slightest reference to Indian or Eastern wheat, though under most commodities he gives important chapters, such as The Present State of the Tea Trade, The Rise and Progress of the Trade in Sugar, etc.

Asiatic rather than European.

Cultivation in India.

Spelt.

Surat Bread.

Deccan Wheat.

Species, Varieties, and Races of Wheat.—The distinction between Spring wheat (*T. aestivum*) and Autumn wheat (*T. hybernum*) can have no importance, since these names do not denote structural differences, and, moreover, are interchangeable climatic conditions according to the country where grown, and even in the same locality, according to the dates of sowings. If gradually changed, the autumn sowings being year by year made a little later, and the spring a little earlier, autumn wheat may become spring wheat, and *vice versa*. A wheat sown in the autumn in the plains of India, if carried to the temperate Himalaya or to Europe, would have to be treated as a spring wheat.

Species and Races.

In point of actual botanical priority, however, the name *T. aestivum* should be given to both spring and autumn wheats; in other words, to all the wheats that by Lamarck were called *T. sativum*, and by Villars *T. vulgare*.

According to some writers, the assemblage of the so-called true wheats has been evolved from *T. monococcum* (Vilmorin, *l.c.* 21, t. 156), a plant indigenous to Servia, Asia Minor, the Crimea and the Caucasian area of Mesopotamia. As its botanical name implies, it is characterised by the presence of but a single seed within the little ear, and its other structural characters place it as a form of spelt rather than of wheat proper; indeed it is often called "small spelt." It has a pale green colour and a flat, short ear. It is, however, still cultivated in Spain, and more rarely in France and Germany. The grain is not often used for bread, but rather for mush, and the plant is valued as a cattle fodder. The yield is said to be from 25 to 35 bushels an acre. Vilmorin would appear not to have been successful in his attempts at crossing this with other wheats. Moreover, Hackel and most modern authors regard it quite unconnected with the true wheats, and entirely infertile with them. Hackel accordingly refers the important grain-yielding forms of *Triticum* (apart from *Ægilops*), to the following chief forms: *T. monococcum*, *T. sativum* and *T. Polanicum*. Having isolated *T. monococcum* by itself, he then proceeds to speak of *T. sativum*, and observes that under cultivation many races have been produced, of which those with the rachis articulated are most probably nearest related to the original stock, whatever that may have been. The brittle-

ono-coccum.

ness of the rachis exists, however, in different degrees, and is correlated with the more or less firm closing of the glumes. Hence he isolates the forms of *T. sativum* into :—

ativum
Spelta.

(A) Rachis articulated at maturity and grain firmly enclosed by the glumes : (a) spikes loose, almost four-sided = *T. sativum*, var. *Spelta*, and (b) spikes very dense, laterally compress = *T. sativum*, var. *dicoccum* (= *T. amyleum*, Seringe, also *Vilmorin*, l.c. 21, tt. 152, 154). Two-grained spelt is grown in certain parts of Southern Europe and is sown in spring. Its grain is used chiefly in the manufacture of starch.

Both the forms (or groups of forms) thus indicated approximate closely to *T. monococcum*, however, and according to De Candolle and other writers, that species may be but the ancient form of the spelt wheats (*Spelta* and *dicoccum* just mentioned).

Awne'd and
Aw'less.

Spelt wheat (*T. Spelta*, Linn., *Vilmorin*, l.c. 20, 146, 148, 150) is, in fact, one of the oldest grains, and there are awne'd and aw'less, hairy and glabrous, also white, grey and reddish-coloured forms of it. It was in ancient times the chief grain in Egypt and Greece and was cultivated everywhere throughout the Roman Empire. Its cultivation has been largely discontinued, and, except in Northern Spain, is unimportant in Europe. In India its cultivation is met with from Sind to Mysore, especially in Bombay. Apparently the first definite intimation of the existence of this wheat in India was made by Buchanan-Hamilton, and subsequently by myself in the *Journal Royal Agricultural Society of England* (1888, xxiv., 36-8). A long and interesting account of it was published by the late Mr. E. C. Ozanne in the *Statistical Atlas of Bombay* (an account reprinted by Lisboa, *List. Bomb. Grass., etc.*, 1896, 129-30). It is known in India as *kaphle* (or *khaphle*), a name which is said to denote the difficulty experienced in separating the grain from the husk. It is also called by other names, such as *jod*, *hotte godhi*, and *pamban*. Its value lies very largely in the fact that it is grown during the *kharif* season, all the other wheats being *rabi* crops. Hamilton speaks, however, of two seasons of cultivation in Mysore. It can be profitably raised on poor soils, where the other wheats could not be grown. Its demands, says Hackel, are less, its liability to disease lower, and the grain being firmly retained within the glumes, makes it proof against the attacks of birds. According to Hamilton, *T. monococcum* (*jave godhi*) and *T. Spelta* are the two wheats of Mysore, and Mollison, in the opening paragraph of his article on wheat (*Textbook Ind. Agri.*, 1901, iii., 24), mentions *T. monococcum* as a wheat "said to be cultivated." (See Mysore below, p. 1099).

Kaphle.

Kharif.

Polonicum.

In this place it may be useful also to dispose of *T. Polonicum* (*Vilmorin*, l.c. 20, and t. 144)—Polish wheat. It is a very striking species with large compressed, mostly bluish-green (glaucous) spikes, readily distinguished by its empty glumes, which may be one inch long and enclose all the flowers of the spikelets. Hackel suspects that it is, perhaps, not a true species, but may have originated by culture. But Poland is, however, by no means its native country. Perhaps Spain, where it is still cultivated on a large scale, has a stronger claim. It is also met with in Italy and Abyssinia, but apparently is not grown in India. It much resembles in its long and slender fruit some of the forms of rye, and is in fact, often sold under the name of Giant Rye.

This leads now to the consideration of Hackel's group—

ativum
tenax.

(B) Rachis not articulated at maturity, grain visible between the open fruit glumes and thus readily falling out. This he distinguishes as *T. sativum*, var. *tenax*, which he further says is referable to four imperfectly characterised races. These may be indicated thus :—

1. *Empty glumes distinctly keeled on the upper half, rounded below :*

* Spikes long, more or less loose in *T. sativum*, race *vulgare* (*Vilmorin*, l.c. tt. 28-122).

** Spikes short, dense, distinctly four-sided in *T. sativum*, race *compactum*.

2. *Empty glumes, sharply keeled at the base :*

*** Fruit short, thick, not compressed in *T. sativum* race *turgidum* (*Vilmorin*, l.c. 18, tt. 28, 130, 132, 134).

**** Fruit oblong, narrow, somewhat laterally compressed and acute in *T. sativum*, race *durum* (*Vilmorin*, l.c. 19, tt. 136, 138, 140, 142).

aces :
Vul are.

The race to which Hackel thus restricts the name *vulgare* embraces numerous forms, such as aw'less and bearded, naked and hairy, white, bluish and reddish spikes. It is perhaps one of the oldest of the modern wheats and the most valuable in Europe, America, India and Australia. Several hundred forms

VARIETIES AND RACES

Triticum Vulgare Practical Aspects

of this wheat have been described. They are commonly grouped into red and white. The white, as a rule, requires a good soil and a dry climate. The red can endure much wet weather, but the red and white forms are interchangeable with altered environment. A better classification is perhaps into beardless and bearded forms.

The race **compactum**—the dwarf or hedgehog wheats (the latter name being given to the awned forms)—is cultivated in the Austrian Alps, Wurtemberg, Alsace, Switzerland, Chili, Turkestan and Abyssinia. They are specially adapted to stormy regions, and are at the same time profitable on soils where other wheats could not be grown. They have short stiff straw.

Compactum.

The form to which the name **turgidum** or Rivet Wheat has been assigned is generally designated English Wheat on the continent of Europe. It has dense, four-sided spikes, the leaves are broader than in *vulgare* and usually velvety, and it affords long, rigid, nearly useless straw. The grain is generally red-coloured, short and thick, with a blunt apex. It is rich in starch but poor in gluten, and for bread-making the flour has to be mixed with more glutinous wheats. This class of wheat is largely grown in the Mediterranean countries, more rarely in England and Germany. English wheat gives a good harvest, but the flour is poor in gluten and usually greyish in colour. The so-called Miracle Wheats (Egyptian wheats) constitute a sub-race under **compositum** and have branched spikes.

Turgidum.

Lastly, the race or group of forms designated **durum** comprehends all the hard spring or flint wheats—the Macaroni Wheats. They are recognisable by their long, bristling awns, almost solid culms, very hard, pointed, usually vitreous, rarely mealy grains, and often black awns. Cultivated in the Mediterranean countries and Asia Minor, and are most important in Spain and Northern Africa. The grain is specially rich in gluten, hence their being largely used in the manufacture of macaroni.

Durum.
Hard Spring
Wheats.

At the third Hybrid Conference held in London during 1906, Philippe de Vilmorin of Paris put the position regarding the origin of the forms of wheat thus—"When my father began, in 1878, cross-fertilisation between the different types of wheats, the object he had in view, and which he fully proved, was that all our wheats—with the exception of *Triticum monococcum*—came from one and the same common origin. In consequence of his experiments, he was able to base his argument on two well-proved facts, namely:—(1) that the six species (*T. sativum*, Lam., *T. turgidum*, L., *T. durum*, Desf., *T. Polonicum*, L., *T. Spelta*, L., and *T. amyleum*, Seringe) of cultivated wheats can be crossed amongst themselves and give products indefinitely fertile. (2) That on crossing any two of these six, the other four may appear among the results."

Vilmorin.

Hybrids.

Only the briefest possible abstract has been attempted in the foregoing observations regarding the classification of the varieties and races of wheat usually adopted by writers on this subject. The student who may wish fuller details should consult Körnicke and Werner (*Handbuch des Getreidebaues*, 1885, ii., 209–529), where it will be seen several hundred forms are discussed.

[Of. E. M. Shelton in the *Report on the Rust in Wheat Conference* (held in Brisbane, Queensland, 1894); U.S. Dept. Agri. (Botany):—Carleton, *Russian Cereals*, Bull., 1900, No. 23, 12–30; also *Macaroni Wheats*, Bull., 1901, No. 3; Scofield, *Algerian Durum Wheats*, Bull., 1902, No. 7; Carleton and Chamberlain, *Durum Wheats*, Bull., 1904, No. 70; Lyon, *Improv. Quality of Wheat*, Bull., 1905, No. 78; Rept. Third International Conference, 1906, on Genetics (published Royal Horticultural Society).]

Practical Aspects.—From the study of an extensive series of Indian specimens sent to London, some years ago, the late Dr. Forbes Watson propounded the following classification:—(1) white, soft; (2) white, hard; (3) red, soft; and (4) red, hard. The vernacular term *pissi* usually denotes soft wheats, and these are the wheats chiefly exported from India. To a certain extent these four groups are cultivated side by side in the same district, but on the whole a geographical isolation may be perceived. Northern India, for example, produces mainly soft wheats, while Southern India and Bengal grow mainly hard forms. The cultivation of the finer

Classification.

qualities of soft wheats would appear to be for the most part comprised within the upper basins of the three great rivers—the Ganges, the Indus, and the Nerbudda. South of the Nerbudda, the true soft wheats may be spoken of as very nearly unknown. The prevalent wheats of the United Provinces and of some parts of Bihar and Tirhut are soft white, and of the Panjáb soft red. Some years ago the late Col. Wace estimated that out of the 7 million acres of wheat then in the Panjáb, 5 million were under soft red wheats. But the soft red extends farther to the south than the soft white. Hard wheats predominate in the Deccan, Berar and some parts of Bengal, and the less valuable form, hard red, extends farthest to the south, and is the only wheat capable of cultivation in the moist climate of the lower Gangetic delta, in Orissa and in Burma. In many parts of the Bombay Presidency, south to Mysore and Madras Presidency, an extremely hard red wheat becomes prevalent, namely that already mentioned under the name spelt.

Prain (*Note on Races of Beng. Wheat*, in *Dept. Land Rec. and Agri., l.c.*) discusses the value of the characters based on the consistence of the grain—the hard and soft; also the distinction according to colour—white and red; and lastly, the condition of bearded and beardless grains. He finally comes to the conclusion that little reliance can be placed on such distinctions taken by themselves. He, however, points out that white or grey wheats, whether soft or hard, have, as a rule, distinctly broader leaf-blades than have the red wheats, and adds that in Bengal the wheats grown are practically all bearded. Summing up his observation of these aspects, Prain comes to the conclusion that Watson's classification, which combines consistence and colour of grain, is of practical value. The soft white wheats of Bengal are called *dudhia*; the soft red wheats, *jámáli*; the hard grey wheats, *gangájuhí*, and the hard red, *kheri*. Mukerji (*Hand-book Ind. Agri.*) mentions fifth and sixth forms, namely *piusa* and *nanbia*.

In the United Provinces the *daudi* wheat is spoken of as the finest. *Mundia* denotes a white, soft wheat of good quality, which is beardless. This wheat is met with here and there: thus Russell alludes to it in his *Gazetteer of Damoh* as grown in embanked fields, since it requires more moisture and is less liable to rust than the bearded wheats. The account given by F. G. Sly of the wheats of Hoshangabad (*Rept. Land Rev. Settl.*, 1891–1905, 26–7) is probably more or less applicable to the whole of the Central Provinces. “The principal kinds of wheat grown are *pissi*, soft and starchy, white; *jalalia*, hard and glutenous, white; *daodia*, soft and starchy, white; *saharia*, soft and starchy, white; *kathia*, hard and glutenous, red; and *bansi*, hard and red. All kinds are bearded, no beardless wheat being grown, which cultivators say is because birds attack it more freely. At present no less than 80 per cent. of the wheat sown is *pissi*, whereas at last Settlement *pissi* is described as an inferior kind, little sown, *jalalia* and *kathia* being grown in about equal proportions. This remarkable change has been brought about by the export trade, *pissi* being in the greatest demand. *Jalalia* is still preferred for home consumption, because it makes better *suji*.” The cultivation of white soft wheats in most provinces of India has greatly expanded with the foreign demand.

G. A. Gammie (*Provis. Class. of Ind. Wheats, l.c.*) subordinates the characters based on the consistence and colour of grains to the presence

or absence of a beard. He forms six sections :—two of which are beardless and correspond, he says, to *T. hybernum*, Linn. (l.c., tt. i., ii., iii., iv.). These would appear to be for the most part white wheats both soft and hard, though one of them, the *jonaria* group, is described as hard red, and the illustration shows it to be shortly bearded (certainly not beardless). Gammie's third section he designates as the *káli kushal*, *bakshi* or *kahno* wheats, which he identifies with *T. pilosum* (l.c. t. v.). In these, the spikelets are velvety, bearded, and the grains described as hard white, yellow or red. The *bakshi* wheats are almost confined to Bombay, more especially the Deccan, and are not met with in the Konkan. Then the fourth and fifth sections are also bearded wheats, which Gammie regards as being forms of *T. aestivum*, Linn. The former he calls *popatia* wheat (l.c., t. vi.), a form met with mostly in Bombay and the Central Provinces, and possessed of hard yellow or hard red grain. The latter he designates the *daudkhani* wheats (l.c. t. vii.); these are shortly bearded and the grains soft white, hard white or hard red. They are met with in the Panjáb and, Gammie says, may be viewed as the transitional forms between the long bearded and beardless wheats. Lastly, his sixth section (l.c., t. viii.) embraces the various forms of *khapli* already discussed (p. 1084). These, he says, are awned and have a covered, hard red grain. An American correspondent of Gammie's, it would seem, had identified the Bombay *khapli* to be the same as *Emmer* wheat of Siberia—"a variety used to transmit rustproof qualities." But in 1903, Gammie tells us, the *khapli* "became decidedly rusted, so that it has now lost its long-maintained reputation of immunity."

*T. hybernum.**T. pilosum.**T. aestivum.**T. Spelta.*

Hybridised and Pedigree Wheat.—The improvement of the stock of wheat has for many years been recognised as an essential feature of rational cultivation. Recent research would seem to show, however, that not only better but more immediate and more enduring results are likely to be attained by hybridisation of stock than by the tedious process of selection that hitherto has resulted in what are known as pedigree wheats. It is, in fact, not enough to know the species and varieties of *Triticum*; it has become imperative to be able to recognise the races and to successfully cross these in directions ascertained to secure the fixation of properties of value in direct adaptation to environment. For example, the property of certain flours, known technically as "strength," that is to say the capacity to afford a large loaf, has been established as a racial characteristic that may be secured by the adoption of certain stocks, or by their utilisation in hybridisation. At one time it was assumed that strength was due to manuring, to methods of cultivation, to soil and climate, or to season of reaping, but each and every one of these opinions have been tested and found unconnected with the production of "strength." All English wheats are admittedly deficient, but Red Fife Wheat (among others that might be mentioned) has been found not only to possess that property, but to preserve it when grown in England, and to transmit the same when employed in crossing with standard English wheats, such as Golden Drop. [Cf. Hall, in *Journ. Board Agri.*, 1904, xi., 321-33; *Rept. Confer. on Genetics, Roy. Hort. Soc.*, 1906, 384.] In a brief note by Howard (*Agri. Journ. Ind.*, 1906, i., pt. iv., 401-3) it is very properly urged that the first step toward improvement is to secure uniformity. He has accordingly pointed out that in India it is not uncommon to find wheat not only grown mixed with barley, gram and other such

Hybrids.

Strength.

Red Fife.

crops, but to discover several distinct races of wheat mixed in one and the same field.

Properties and Uses.—The methods of employing wheat for human food in India vary somewhat in the different provinces. From the grain, three chief kinds of flour are made, viz. *suji*, *maida* and *ata*. The first is a granular meal obtained by moistening the grain overnight, then grinding it. The fine flour passes through a sieve, leaving the *suji* and bran above. The latter is got rid of by winnowing, and the round, granular meal or *suji* remains. This preparation may be described as a form of semolina, and is most easily produced from the hard wheats rich in gluten. It is employed in confectionery, and in place of oatmeal in making a kind of porridge. The hard white wheats are also valued in the preparation of macaroni. *Maida* and *ata* may be prepared from the flour separated in the preparation of *suji* by regrinding it and passing it through a finer sieve than used formerly, the finer flour that passes through being *maida* and the coarser *ata*. They are, however, most largely prepared without going through the process of separation of *suji*, the dry grain being at once ground and sifted into the two qualities. *Maida* is the luxury of the rich while *ata* is the flour of the poor and is generally cooked in the form of coarse cakes—*chapattis*—toasted by the side of an open fire. These are eaten along with *dal* and *ghi* or other relish, and constitute the chief food in the wheat-consuming tracts of India. In many localities, however, the *ata* is not obtained from pure wheat but from a mixture of wheat-barley or wheat-gram, the two grains being ground in the mixed form—a habit that has led to cultivation of the mixed crops already alluded to and also to the sale of the mixed grains, a condition by some persons incorrectly regarded as deliberate adulteration. In the larger towns of India, bread and biscuits, prepared from flour leavened and baked in the European fashion, have come greatly into use and seem destined to even more general consumption. But the fermenting of wheat flour in the manufacture of bread seems to have been unknown prior to the advent of the Europeans. The uses of wheat in the arts and medicine need hardly be detailed. Wheat starch is, as a rule, too expensive for extended use in India. Like that of rice, the gluten mixed with fine lime is employed as a special cement. For microscopical results consult Hanuasek (*Micro. Tech. Prod.* (Winton and Barber, transl.), 1907, 37, 334-49).

Adulteration of Indian Wheat.—The opening of the Suez Canal brought India into direct touch with Europe and demonstrated the possibility of Indian wheat and other foodstuffs being conveyed to Europe in thirty days. Prior to 1870, no mention occurs of India's participation in the world's supply of wheat. And when it did appear in the corn markets of Europe, it was viewed by many as introducing an undesirable disturbing element which it became necessary to ward off rather than to encourage. The delusion that rice was the staple food of India, and, therefore, her chief agricultural (food) crop, seems never to have been more rudely dispelled than by the emphatically demonstrated fact that India not only grew wheat, but was prepared to contest certain markets and to land special wheats at a price lower than they could be produced elsewhere. This was first met by the outcry that, for greed, the better classes of the community were exporting the surplus stocks that formerly were stored against times of scarcity and famine. When this failed, the tendency to uncleanly wheat, instead of being removed by emulation, was stereotyped.

ADULTERATION OF INDIAN WHEAT

TRITICUM
VULGA

Mud and seeds

into "refraction"—in other words, percentages of impurity were standardised as unavoidable and therefore permissible, below which no enhancement of price was paid but above which deductions were authorised. The practical effect of this system was the payment of freight on mud and the charges for cleaning in Europe, both of which told against India's success as a wheat-supplying country for Europe. Viscount Cross, at a meeting held at the India Office in 1889, pointed out that an enormous amount of dirt was in this way imported annually and freight paid on it as if it were wheat. Assuming an average of 3 per cent. adulteration, that would come, on the 1905-6 exports of wheat conveyed to the United Kingdom, to half a million cwt. of mud, on which freight and other charges had to be paid. Voelcker (*Improv. Ind. Agri.*, 277-8) and others have shown that this state of affairs is in no way due to bad cultivation nor to careless threshing on the part of the Indian cultivators, but is entirely a consequence of deliberate adulteration to suit the requirements of the English corn trade. A similar state of affairs characterised the American wheat trade, since the wheats that first came into Europe contained as much as 10 per cent. of prairie oats, rye and other impurities. It was sold on a standard of "fair average quality" (f.a.q.). But the American producers soon saw the necessity for reform and turned out a clean wheat, and were thus able to establish the standards of sale on their own side of the Atlantic. So far, India has failed to attain that position, though more than one effort has been made to remedy the evil of adulteration both by the Government of India and the Indian merchants.

F.A.Q.

In an official dispatch, dated November 29, 1906, the Government of India sum up the present position and then add that "The replies received have been considered, and the Government of India now feel justified in announcing for general information that, if buyers of Indian wheat desire to obtain regular supplies containing not more than 2 per cent. of impurities (that term covering all foreign matter other than food-grains) the mass of Indian shipments can be made on that basis."

Future
Position

By the opponents to reform, it has been upheld that Indian wheat is of necessity less pure than the wheats of Europe, America and Australia, due to the imperfect methods and appliances of the Natives; that accordingly it has to be washed, and may as well contain 2 per cent. impurity as one. But if the shippers are prepared to do the cleaning in India, a saving in freight would be effected that might go a long way toward covering the cost of cleaning and, moreover, Native methods might easily be improved. The demand for pure wheat to be made by the buyers in Europe would accordingly seem the natural and only solution of the present anomalous state of affairs, if the further position be not upheld as the ultimate result of the controversy, namely the expansion of the milling interests of India and the export of flour in place of grain (see p. 1101).

Opponents to
Reform.

Demand for
Pure Wheat.

Seeds found in Wheat.—The seeds obtained during Indian wheat screenings are gram, polygonum, rape and *piazi*—the last being a species of *Asphodelus*, which in the Panjáb is often very prevalent in the wheat-fields—especially in the Jhelum districts—and to such an extent as to give much trouble to the cultivators. [Cf. Howard, *Agri. Journ. Ind.*, 1907, i., pt. iv., 403-5; ii., pt. ii., 210.]

Range of Seasons and Crop Adaptations.—The antiquity of wheat cultivation in India can be at once realised by the evident direct adaptations of the forms of the crop grown to the varied conditions of soil and climate under which produced. As indicative of this wide range of racial adaptations to climatic and other conditions, the following passage from a paper written by me on *The Crops and Climatic Conditions of India* (*Agri. Ledg.*, 1895, No. 3, 38) may be here given :—"As a result of these considerations we have the startling state of affairs that a journey from one extreme of India to the other may reveal the cultivators engaged in every stage of the operations connected with certain crops, such as preparing the soil, sowing, watering the advanced crop, reaping, threshing and carrying the produce to market. For example, were the journey made in June from the Panjáb to South India, the cultivators would in the north be found engaged in the early preparation of the land, for the crop to be sown in September to December; in mid journey they would be seen tending the mature *kaple* wheat of the Konkan; and in Mysore and some parts of Madras Presidency, they would be found sowing wheat—a crop that will be harvested in September and thus practically at the very time that the great wheat crop of Northern India is being only sown." In general terms it may be said wheat cultivation increases on passing to the north, in other words, on leaving the humid atmosphere and inundated soils of the south. Indian wheat as a whole might, moreover, be spoken of as comprising a varied assortment of winter wheats, that is to say, the bulk of the Indian crop is sown in autumn and reaped in spring (*rabí* crop), but except on the hills it has rarely to pass through a winter of frost, so that from the climatic standard the Indian wheats might rather be spoken of as spring wheats. Frosts are, however, not unknown, and often do much harm as the grain is ripening. But unlike the spring wheats of Europe, the Indian crop may in general terms be said to ripen with an increasing, not a decreasing temperature. That is to say, from January onwards the approach is rapidly made to the hot season, and by April and May the hottest temperatures of the year are usually recorded. This circumstance, so dissimilar from that of most other wheat-producing countries in the world, may have much to say to the "ricey" character attributed by the trade to the Indian wheats as a whole.

Yield.—The seed is ordinarily sown in October and ripens in three and a half to four months—a good average crop would be about 800 lb. to the acre. But there may be said to be two subordinate groups, namely dry-crop wheats and irrigated wheats. The increased facilities of canal irrigation account largely for the recent expansion of the area and production of irrigation wheats in the Panjáb. The possibilities of the future in this direction cannot by any means be regarded as definitely established. Irrigation wheat on land liberally manured may yield from 1,200 to 1,600 lb. an acre.

Associated Crops.—To a large extent wheat is in India interchangeable with other *rabí* crops, such as linseed or gram, and it is accordingly rotated with these and may be sown alone or mixed with barley or gram or with intervening rows of mustard or safflower. The value of a rotation with leguminous crops is fully understood by the Indian cultivator and universally taken advantage of all over the wheat area. Recently Howard (*l.c.* ii., pt. ii., 210) has pointed out that in the Eastern Panjáb it is

customary to sow *senji* (*Melilotus parviflora*) among cotton, so as to raise a *rabí* forage crop. It is commonly seen also among wheat (*Fodder*, in *D.E.P.*, iii., 416).

Diseases.—So much has been written on this subject, even in connection with India alone, that many pages would have to be devoted to the subject before anything like a satisfactory abstract could be produced. Rust is by far the most important or serious. It is known to the Natives as *geru*, *gerwar*, or *jeru*. According to the belief of the cultivators, it attacks the crops only when sown on irrigated land or when an undue amount of rain falls or heavy clouds prevail, during the early growing stages. For some years the late Dr. Arthur Barclay devoted much attention to the study of wheat rust and arrived at many surprising conclusions, one of which may be here stated, viz. that while the barberry bush of the Himalaya bears abundantly æcidial cluster-cups, which he supposed to be those of *Puccinia graminis*, the rust of the wheatfields is *P. rubigo-vera* (*Journ. Bot.*, 1892, xxx., 46). In the *Agricultural Ledger* (1895, No. 20, 287–98) will be found an illustrated description of the two chief forms of the rust, viz. *P. graminis* and *P. rubigo-vera*, and their various stages of existence. Massee (*Textbook Pl. Diseases*, 1903, 247–9) deals very briefly with black rust and crown rust. A few years ago the Colonies of Australia held a series of conferences on rust in wheat. As a consequence, voluminous reports of the deliberations of the Commissioners were published from 1890 to 1896. These were ably reviewed by Prain (*Agri. Ledg.*, 1897, No. 16). About the same time Cunningham and Prain published a *Note on Indian Wheat Rust* (*Rec. Bot. Surv. Ind.*, i., 99–124), in which they point out that perhaps five species of *Puccinia* attack the wheat of the plains of India. They also describe an æcidial fungus on *Launea*, which they suggested may possibly be the source of the Shibpur wheat rust. Butler (*Dept. Agri. Ind. Bull.*, 1903, pt. i., No. 1) carried the subject a step further by throwing doubt on the æcidial fungus of the Himalayan barberries being at all connected with wheat rust. He then remarks, “I have found that the common *Æcidium* on the barberry at Mussourie is not allied to the wheat fungus, but is a distinct and remarkable species, accompanied by a *Uredo*-form on the barberry itself, and giving rise to witch’s brooms on the attacked bushes. The barberry may be entirely left out of account in India.” He then points out that the *P. rubigo-vera* of Indian writers comprehends several species, more especially *P. glumarum* and *P. triticina*. Under the former he places the Ferozpur wheat rust and the Mogul Serai barley rust of Cunningham and Prain. *P. glumarum* appears earlier than *P. graminis*, and as far as Indian experience goes, is much more destructive to the grain.

The next paper of importance that appeared in India is that by Butler and Hayman, to which is appended a note by Moreland (*Mem. Dept. Agri. Ind.*, 1906, i., No. 2, 1–57, tt. i.–v.). This reviews the main facts already mentioned, then pointedly exhibits the issues that remain unsolved regarding the propagation of rust from season to season (*l.c.* 10), and in the concluding summary speaks of three distinct rusts met with in India, viz. *P. graminis* (black rust), *P. glu arum* (yellow rust), and *P. triticina* (orange rust). All three commonly attack wheat, and the first two barley also. In conclusion, it may be said that these authors see inclined to accept Eriksson’s theory of hereditary infection in

preference to that which involves the discovery of an intermediate "host." [Cf. Butler, *Volunteer Wheat and Rust*, in *Agri. Journ. Ind.*, 1907, ii., pt. i., 99-100; Maxwell-Lefroy, *Mem. Dept. Agri. Ind.*, 1907, i., No. 2.]

AREA OF PRODUCTION.—The chief wheats exported from India are the Muzaffarnagar soft white (*dudhi*) and the Bombay and Central Provinces hard white (*bakshi*) above indicated, but the wheats most popular within India itself are those produced in the Panjáb. With the vast majority of the people of India wheat is not, however, a necessity of life; it is indeed rarely if ever eaten by them. Wheat becomes an important article of food in the Panjáb only. In India as a whole, therefore, its cultivation is governed more by external than internal considerations. When the markets of Europe give indications of profit, its cultivation is immediately increased. But the mere fact of a definite proportion of this foodstuff being produced as an article of export (far from being a source of danger) is of the very greatest value to India, since, when the necessity arises, exports can be stopped by increased local demand and a new source of food thereby rendered available. It is not to be wondered at, therefore, that exceptionally good harvests in Europe and America are immediately followed by lessened cultivation in India. The effect of famine on wheat exports may also be clearly demonstrated:—The exports for the ten years ending 1899-1900 averaged 12½ million cwt.; in 1900-1, a year which followed a serious famine, the exports were only half a million cwt., and two years later (1903-4) they expanded to 26 million cwt. If wheat displaces any crop it would be cotton, certainly not the food-grains of the people. Few cultivators are likely to be found so ignorant as to grow the millets on the rich lands on which alone wheat and cotton can be successfully produced. The best lands have always been devoted to rent-paying crops, that is to say, to export crops—such as oil-seeds, wheat and cotton—and only during times of famine would these lands be thrown under the millets and other necessitous food crops.

From these and such like considerations it may readily be understood that the area in India (British and Native States) normally under wheat manifests extreme fluctuations. Thus in 1891-2 it was 27,032,772 acres with a production of 6,093,741 tons of wheat; in 1893-4 it stood at 28,716,735 acres with 7,268,982 tons; in 1895-6 it had fallen to 24,071,320 acres with a production of 5,380,342 tons. Then it rose in 1898-9, and in the very next year, 1899-1900, fell to 18,687,782 acres with 5,357,142 tons. For the three succeeding years it fluctuated around 23 million acres, and in 1903-4 suddenly expanded to 28,413,743 acres with 9,641,145 tons; and in 1905-6 stood at 26,226,200 acres with a production of 8,560,340 tons. The *Final Memorandum* for 1906-7 estimates the area at 29,444,200 acres, but the yield at only 8,508,040 tons.

The provincial distribution of these acreages may now be discussed. The PANJÁB (including the North-West Frontier Province) heads the list with its lowest area (in recent years), namely 6,223,600 acres in 1891-2 and its highest record, 10,184,200 acres in 1906-7, with a production of 3,588,100 tons. During the past six years it has shown an average of over 8½ million acres under the crop, and has manifested on the whole a steady expansion. Then follow the UNITED PROVINCES, which normally fluctuate between 6 and 7½ million acres. The CENTRAL PROVINCES stand next in order, with a normal area of from 2 to 3 million acres and Berar adding about half a million more. Then comes Bombay with from 1½ to 2 million

CHIEF INDIAN AREA

T ITICU
VUL A
Cultivation

acres, while SIND and its Native States add to the Bombay Presidency about half a million more acres. Lastly Bengal (including Eastern Bengal) normally possesses about $1\frac{1}{2}$ million acres. Except in the Panjáb, therefore, the area in the other provinces cannot be regarded as giving any indication of expansion.

The NATIVE STATES have collectively about 5 million acres under wheat. The *Final Memorandum* issued by the Commercial Intelligence Department estimates their area for 1906-7 at 5,176,000 acres, with a production of 1,048,540 tons. The largest proportion is in Hyderabad and Rajputana, which each have on an average 1 million acres, while Central India has approximately 2 million acres. Included under these areas mention may be made of Gwalior, which during the past five years has had from 298,872 to 726,674 acres under the crop; Bhopal in 1905, 419,766 acres; Indore, 287,681; Bandelkhand, 215,468; Bhagalkhand, 289,128 acres; and, lastly, Kotah has annually from 100,000 to 300,000 acres of wheat.

Panjáb and North-West Frontier.—One-third of the total cropped area of the Panjáb is usually under wheat, an area which represents about 29·3 per cent. of the total wheat area of British India. According to the *Agricultural Statistics*, the actual wheat area in the Panjáb in 1904-5 was 7,681,700 acres and in the North-West Frontier 821,586 acres, the yield having been 3,122,900 tons. In 1905-6 the total area for the two provinces was 9,596,700 acres and the yield 3,790,000 tons, while the *Final Memorandum* for 1906-7 estimated the area and yield, as already mentioned, at 10,184,200 acres and 3,588,100 tons. As representative of distribution, it may be added that during 1904-5 the following districts in the Panjáb had each over 300,000 acres of wheat:—Lyallpur, 591,818; Ferozpur, 565,433; Lahore, 438,360; Attock, 407,768; Siálkot, 396,837; Gujránwála, 363,367; Amritsar, 350,397; Sháhpur, 342,483; Gurdáspur, 330,586; Jhelam, 325,793; Gujrat, 310,725; and Multan, 305,051. In the North-West Frontier the areas are smaller, the chief being—Peshawar, 299,347 acres; Bannu, 209,136; and Hazara, 122,068.

The crop is sown on what are known as *rausli* and *rohi* lands; the former are light, easily pulverised loams, very prevalent in Upper India; the latter, rich well-drained soils approaching what is known as *dákar*. *Dákar* proper is as a rule too heavy and not sufficiently drained for wheat. The crop occupies the soil for about six months—the first sowings are made by the middle of October, and the harvest operations are completed by the latter end of May. The systems pursued vary to some extent locally, but mainly in consequence of the nature of the soil and source of water supply. The following particulars derived from *Hoshiarpur District Gazetteer* (1905, 93-5) is representative of the Panjáb generally. The common wheat grown is a reddish bearded variety called *káthi*, the kind most commonly used for mixtures with gram and other crops. "The number of ploughings given to wheat varies according to the crop that precedes it. If it follows maize, the time for ploughing is short, and not more than three or four can be given. If the two-year course is followed, continuous ploughings can be given for ten months; but even so, the majority of farmers do not plough more than eight or ten times. The best time for sowing is from the middle to the end of October, but wheat can be sown up to the end of December. In the riverain villages the land is often not dry enough to sow till November, and if the seed is sown too early it is eaten by a small grasshopper called *toka*. The subsequent

operations are simple. The field should be occasionally weeded in November and December. After December, nothing need be done besides the protection of the crop from stray animals till it is ripe in April. About the middle of April is the proper time to begin reaping the wheat harvest."

Seed to Acre.

"The quantity of seed used is half a maund per acre, but a good deal depends on weather conditions at the time of sowing, and also on the class of soil. The average outturn varies much from tract to tract. Extensive crop experiments were carried out for five years during the First Revised Settlement, and the results seem to show that in the best plains Tahsils, the average produce is 8 to 9 maunds an acre; in Dasúya about 7 maunds; and in the hills only 4 maunds." Of course the difference is enormous between the outturn of the best land, highly manured, 12 to 14 maunds, and that of the poorest sandy soils or badly manured land, 6 to 9 maunds. "In the light soils of Kandi the yield falls in bad years to 3 or 4 maunds per acre."

Averages.

According to the *Agricultural Statistics*, the average yield per acre in the Panjáb for a period of five years ending 1901-2 was 935 lb. irrigated and 642 lb. unirrigated land, and in the North-West Frontier, 883 lb. on irrigated and 563 lb. on unirrigated. In the Panjáb the largest yields were obtained in Gurdáspur, Amritsar, Jalandhar, Ferozpur, Delhi, Ludhiana, Lahore, Ambala and Mianwali; and in the North-West Frontier in Dera Ismail Khan, in all of which average yields of over 1,000 lb. (12½ maunds) per acre have been recorded on irrigated lands.

[*Cf. Wace, Panjab Wheat* (Panjáb Govt. publicat.), 1884; *Dist. Gaz.; Repts. Oper. Dept. Land Rec. and Agri.; Settl. Repts.; Repts. Agri.-Hort. Gardens, Lahore*; Howard, *Weeds in Panjab Wheat Fields, Agri. Journ. Ind.*, 1906, i., 403-5.]

U. Prov.

United Provinces.—The crop is very important in these provinces, ordinarily occupying about one-fifth of the net cropped area, an amount which on an average of the five years ending 1904-5, represented 27·9 per cent. of the total wheat area in British India. According to the *Agricultural Statistics*, the area in Agra in 1904-5 was 5,533,542 acres and in Oudh 2,197,224 acres, giving a total of 7,730,766 acres. The outturn for the same year was estimated at 1,897,000 tons. In the *Final Memorandum* on the crop for 1906-7, the area is stated to have been in 1905-6, 6,478,900 acres and the yield 2,428,700 tons; and in 1906-7, 7,039,100 acres and 2,164,500 tons. In Agra the largest areas are usually in the Meerut and Rohilkhand Divisions. In the former, Meerut district had 383,916 acres in 1904-5, Saharanpur 355,272 acres, Muzaffarnapur 276,864 acres, Bulandshahr 258,377 acres, and Aligarh 229,100 acres; in the latter (Rohilkhand Division), Moradabad had 383,555 acres, Budaur 344,345 acres, Shahjahanpur 276,703 acres, and Bareilly 222,895 acres. In Oudh—Lucknow Division—Hardoi had 320,938 acres, Sitapur 269,836 acres, and Kheri 221,264 acres. In Fyzabad Division, Gonda had 277,487 acres, and Bahraich 247,823 acres.

No general statement regarding cultivation has been published since the *Field and Garden Crops* appeared, but the annual reports of the Cawnpore Experimental Farm and the bulletins issued by the Agricultural Department contain much valuable information, especially regarding the experimental manuring of wheat. The crop is entirely a *rabí* one being sown at the end of October or beginning of November, and cut in March and April. According to Duthie and Fuller, it is grown o

YIELD PER ACRE

T ITICU VULGA Cultivation

almost every soil, except the lightest sands, but a rather heavy loam is considered best. The better class of wheat-fields are manured every second or third year, and the land is sometimes prepared by herding sheep on it. As a rule, wheat is sown only on land that has lain fallow during the preceding *kharif* (known as *chaumas* or *pural*), but in highly manured lands near village sites it occasionally follows maize. No particular rotation is known to be pursued, but in tracts where cotton is widely grown, wheat is generally said to follow. In the Meerut district an elaborate rotation is practised in which wheat is grown only twice in five years. On an average the land is ploughed about eight times before sowing. The seed rate is said to vary from 100 to 140 lb. per acre. After sowing, the field is divided into irrigation beds. If the soil is sufficiently moist in October to allow of the seeds germinating properly, the necessity for irrigation will depend on the occurrence and extent of the winter rains. Should the soil be too dry for germination, a watering (called *paleo*) is given before sowing. As a rule, three or four waterings are said to be ample even in the driest localities. As regards outturn, it has been estimated that 15 maunds per acre for wheat grown alone, as also for wheat-barley, and 13 maunds for wheat-gram, are the lowest averages which could be taken. According to the *Agricultural Statistics*, the average yield for the whole province for the five years ending 1901-2 was 1,250 lb. (15 maunds) per acre for irrigated wheat, and 800 lb. (9.75 maunds) per acre for unirrigated. The largest average yields during that period were obtained in Bulandshahr and Bahraich, viz., for irrigated wheat, 1,300 lb. per acre, and in Bahraich and Naini Tal, viz., for unirrigated, 1,050 lb. and 1,000 lb. respectively.

[*Cf. Wright, Rept. on Wheat Cult. and Trade in U. Prov., 1878; Duthie and Fuller, Field and Garden Crops, 1882, i., 1-8, tt. 1-2; Leather, Exper. on Wheat and Maize, Dept. Land Rec. and Agri. U. Prov. Bull., 1900, No. 9; also Exper. on Growth of Wheat (a) with Green Manure (b) in Rot. with Legum. Crops, No. 10; Moreland, Australian Methods of Test. and Improv. Wheat, in Agri. Ledg., 1901, No. 2, 11-31; Nevill, Dist. Gaz. U. Prov., 1903-6; Numerous Repts. of Exper. conducted at Cawnpore Exper. Farm; also Repts. Govt. Bot. Gard., Saharanpur, and Hort. Gard., Lucknow.*]

Central Provinces and Berar.—In these provinces wheat occupies about one-eighth of the total cropped area, a figure that represents 11.4 per cent. of the total wheat area of British India. The actual area in 1904-5, according to the *Agricultural Statistics*, was 3,070,421 acres in the Central Provinces, 427,236 acres in Berar, and estimated yields 751,900 tons and 80,000 tons. The *Final Memorandum* on the crop for 1906-7 states the combined area and yield to have been in 1905-6, 3,443,800 acres and 834,400 tons; and in 1906-7, 3,689,800 acres and 904,700 tons. According to the figures for 1904-5, the districts with largest areas expressed in acres in the Central Provinces were Hoshangabad, 424,588; Jabbalpur, 362,354; Saugor, 332,788; Seoni, 261,674; Nagpur, 214,258; Chhindwara, 197,767; Damoh, 191,511, etc. In Berar—Buldána, 145,582; Bâsim, 98,862; Amraoti, 67,429, etc.

The system of cultivation is practically the same as that pursued in the heavy black soils of Bombay (see below). Unlike the United Provinces and Panjâb, manure and irrigation are here unimportant. For ordinary wheat cultivation, preparatory operations commence in April or May and the field is ready for sowing by October. The seed rate varies from 80 to 120 lb. per acre. The crop is left entirely to itself till

harvest in the beginning of March. A different system is pursued in a tract of country which includes a considerable portion of the Jabbalpur and a small portion of the Narsinghpur and Seoni districts. The fields are surrounded with banks, and rainwater is allowed to accumulate in them. The water is let off at the beginning of October, and the seed is then drilled in without any preliminary preparations. The average outturn for the province for the five years ending 1896-7, according to the *Agricultural Statistics*, is estimated to have been 925 lb. per acre for irrigated wheat, 570 lb. for unirrigated. Returns for irrigated wheat are given only for Betul, Chhindwāra, Nagpur and Nimar.

The method of cultivation pursued in Berar differs but little from that in the Central Provinces. It is sown in October and reaped in February, and is cultivated in rotation with other crops. The *Agricultural Statistics* give an average yield, for a period of five years ending 1901-2, of 687 lb. per acre.

[*Cf. Land Rev. Settl. Repts. ; Nagpur Exper. Farm Repts. ; Fuller, Note on Outturn of Land under Principal Crops in C. Prov., 1894, 4-10 ; Russell, Dist. Gaz., 1906, A, 87-90, 101-2, 105-7 ; Clouston, Man. Exper. with Wheat at Nagpur Exper. Farm, in Agri. Journ. Ind., July 1906, i., pt. iii., 205.*]

Rajputana and Central India.—The returns published annually in the volume of *Agricultural Statistics* would appear to give actual areas for which definite surveys have been made. The figures, on the other hand, published by the Commercial Intelligence Department would appear to be forecasts and estimates. According to the former, the area in 1904-5 in Central India and Rajputana (viz. Gwalior, Jaipur, Bikanir, Marwar, Tonk, Alwar, Kishengarh, Bharatpur, Jhalawar and Kotah) came to 1,277,872 acres, with Ajmir-Merwara adding 17,167 acres. According to the latter (the Commercial Intelligence Department), particulars of other States are afforded, and thus manifest larger areas, viz.—2,171,019 acres in Central India and 1,023,773 acres in Rajputana, with yields of 472,658 tons and 188,981 tons respectively. Accordingly, if we accept the areas given in the estimates for Central India and Rajputana as approximately correct and add to them the area for Ajmir-Merwara from the *Agricultural Statistics*, we would obtain a total of 3,211,959 acres under wheat in 1904-5. The *Final Memorandum* on the crop for 1906-7 states the area to have been in 1905-6, 1,852,100 acres with a yield of 420,600 tons in Central India ; 604,000 acres and 145,000 tons in Rajputana ; and in 1906-7, 2,895,000 acres and 639,800 tons in Central India ; and 810,000 acres and 215,000 tons in Rajputana. In Central India the most important districts are Gwalior, Bhopal, Indore, Bandelkhand, Bhagalkhand and Bhopawar ; and in Rajputana—Kotah, Jaipur, Tonk and Bharatpur.

There is little information regarding cultivation available beyond the facts given above. The climate and soil closely approximate to the Panjāb on the one hand and to the Central Provinces on the other, and the wheats are accordingly similar. In Ajmir-Merwara the best land is said to be selected for wheat, generally near a tank or well. To obtain a full crop, the land is fallowed during the rainy season (June to September), and is ploughed two or three times. Sowing begins about the end of October and lasts till the end of November, the crop being reaped in April. The quantity of seed sown is said to be about 2 bushels per acre, and the outturn, if the crop be manured and irrigated, is about 34 bushels.

o bay and Sind.—The area in the British districts of Bombay and

WESTERN INDIA

T ITICU VULGA Cultivation

Sind represents about one-eleventh of the total net cropped area of the Presidency, or about 7.2 per cent. (Bombay), and 1.9 per cent. (Sind) of the total wheat area in India. The areas in 1904-5, according to the *Agricultural Statistics*, were 1,749,182 acres in Bombay, 491,413 acres in Sind. The *Final Memorandum* for the same year, issued by the Department of Land Records and Agriculture, estimates the area in the British districts of Bombay at 1,611,197 acres, and in Sind at 479,629 acres, while in the Native States the area is stated to have been 535,444 acres, giving a total (including Native States) of 2,626,270 acres. The total yield is estimated at 469,134 tons. The *Final Memorandum* for 1906-7 states the area and yield to have been in 1905-6, 1,975,353 acres and 471,357 tons; and in 1906-7, 2,219,763 acres and 504,827 tons. The largest areas, expressed in acres, in the British districts of Bombay in 1904-5, were Khandesh, 393,815; Nasik, 271,091; Ahmadnagar, 243,630; Dhárwár, 243,262; Bijápúr, 144,328; and Ahmadabad, 100,708. In Sind, Thar and Parkar, 122,165; Sukkur, 118,421; and Lárkhána, 114,930. In the Native States, Kathiáwár, with an acreage of 241,932, is the largest area.

Area.

Yield.

Districts.

Lisboa (*Bomb. Grass.*, 1896, 130-1) makes some interesting remarks regarding the wheat area in Bombay. He states that the wheats grown are not largely in demand in England, and further that there is little prospect of the area being materially increased. He argues, accordingly, that the growth of wheat is not so greatly influenced by the prices ruling in Europe as some suppose. Being a late-sown crop (October) its area rather depends on the amount of suitable land available after cotton and the early cereals have been provided for. Moreover, as there are not extensive areas of land now uncultivated that are fit for wheat, he holds that the extension of railways in the Presidency and the brisk export demand will not have such an effect in encouraging the growth as some writers allege. Nevertheless, since 1896 the wheat area of the British districts of Bombay has, if anything, steadily improved.

Wheats not in Demand.

Dependent on Cotton.

The methods of cultivation pursued in the Presidency have been fully discussed by Mollison (*Textbook Ind. Agri.*, 1901, iii., 25-8). "It is extensively grown as a dry crop on deep, black, moisture holding soil. The finest dry crop lands of the Presidency are along the Tápti in Khándesh, in the plains of Kopergaon and along the Godavery in Ahmednagar." As an irrigated crop it does best on lighter soil. "Medium black soil, so common in the Deccan, is very suitable." The dry crop is either grown alone or with subordinate rows of safflower. In Panch Maháls, wheat and gram are grown together. Irrigated wheat is usually unmixed. The dry crop "is grown continuously in some parts of Ahmednagar, Ahmedabad and Nasik. In the cotton districts of Khándesh, Dhárwár, Broach, etc., it is rotated with cotton and *juár*. In the deep black soil which borders the Tápti in Khándesh, it is rotated with linseed and gram. In the Panch Maháls on land brought under tillage during recent years it follows a *kharif* crop of maize, the land being double cropped annually."

Dry Crop. Soils.

Black Soils.

Rotation.

In the case of dry-crop wheat, preparatory tillage begins usually before the rains, and the soil is worked into a friable condition so that it may readily absorb the monsoon rain which falls in June, July and August. It is not often manured, but if manure be given, it should be applied in August or September and mixed with the soil by a light ploughing.

Seasons.

Manure.

Irrigation.	It should be sown in October, and the seed for dry-crop wheat is always drilled. The rate varies from 40 to 55 lb. per acre. Irrigated wheat, on the other hand, "is sometimes broadcasted, sometimes drilled and occasionally sown by hand in the furrows behind the plough." The seed
Seed Rate.	rate is higher than for dry wheat; "70 to 80 lb. per acre are ordinarily sown, and in the case of spelt wheat in husk, 100 lb." After sowing, the crop requires little attention beyond regular irrigation.
Outturn.	"The outturn of grain varies much with the season. A well-managed irrigated crop produces about 2,000 lb." (24·4 maunds) "grain and over a ton of straw, whilst a good dry crop will not often exceed 1,000 lb. of grain and about the same weight of straw. 600 to 650 lb. grain per acre probably represent a full average crop in an ordinary year from deep, black soil, cultivated in the ordinary manner."
Cost.	The cost of cultivating dry wheat in Khandesh, Mollison estimates at Rs. 12-7a. per acre.
ind.	Sind may be said to be intermediate between Bombay and the Panjáb as regards wheat cultivation. In parts of the country, the methods of cultivation, the nature of the soil and the character of the wheats are similar to those in the Panjáb, but in other parts an approximation to the wheats of Northern Bombay is seen. The Sind wheats are generally
Superior.	said to be superior to those of Bombay, and possess a larger proportion of soft white forms. Most of the Sind wheats are, as in the Panjáb, repeatedly watered or flooded during their growth. A dry crop is, how-
Outturn.	ever, raised on lands that are inundated during the rains. For a period of five years, ending 1901-2, the average outturn in Sind, according to the <i>Agricultural Statistics</i> , was 1,066 lb. per acre.
	[Cf. Monteith, <i>Wheat Cult. in Bombay Pres., Govt. Publicat. Rev. Dept., 1883</i> , No. 505; Lisboa, l.c. 128-34; <i>Rept. Director Bot. Surv. Ind., 1902</i> , 8; <i>Crop Exper., Bomb. Pres.; Repts. Dept. Land Rec. and Agri.; Exper. Farm Repts., Poona, Manjri, etc.</i>]

Area.	tons. This represents only about 2 per cent. of the net cropped area of the province. The <i>Final Memorandum</i> on the crop for 1906-7 states the area and yield in Bengal (excluding Eastern Bengal) to have been
Yield.	in 1905-6, 1,248,300 acres and 396,600 tons; and in 1906-7, 1,402,600
Districts.	acres and 388,700 tons. The districts of the Patna Division ordinarily contain about one-half of the total area, amounting, in 1904-5 to 746,300 acres, and those of Bhagalpur about one-third, or 422,100 acres in 1904-5. The areas in the other divisions were:—The Presidency, 120,900 acres; Rajshahi, 113,600 acres; Chota Nagpur, 36,000 acres; Bardwan, 14,000 acres, etc. According to the <i>Agricultural Statistics</i> , the average yield has been fixed provisionally at 12 maunds or 984 lb. per acre for the Bihar districts, 10½ maunds or 861 lb. per acre for the Bengal districts, and 451 lb. per acre for the districts of Chota Nagpur.
Soils.	Mukerji states that a "clay-loam, easy of irrigation, situated in a dry locality, is the best soil to choose for wheat"; and again, "The best crops of wheat are grown on land mainly brought under canal irrigation." The land should be prepared for sowing as soon as possible after the rains are over. Sowing should be made when cold weather has
S ons.	been established, say, in November. In rocky and laterite soils, sowing should be done earlier, about the 20th or 25th October, or even earlier still if the rains cease in October. About 100 lb. of seed are used per acre, but
Seed to Acre.	

Mukerji thinks that is too much and that 50 lb. should suffice. After sowing, the field should be laid out in irrigation beds, and one or two floodings given. One hand-weeding should be done within ten days after the first watering, and two hoeings may be subsequently given. The crop is harvested when the grain is quite ripe. Mukerji estimates the cost of cultivation at Rs. 26 per acre and the value of a crop consisting of 12 maunds grain and 16 maunds straw at Rs. 37-8, giving a profit per acre of about Rs. 11.

Harvest.
Cost.

[Cf. Grierson, *Bihar Peasant Life*, 1885, 213-4; *Cult. and Trade of Wheat in India*, Beng., 1886; Basu, *Agri. Lohardaga*, 1890, pt. 2, 30-2; Mukerji, *Handbook Ind. Agri.*, 1901, 237-45; *Admin. Rept. Beng.*, 1901-2, 14-5; Roy, *Crops of Beng.*, 1906, 31-42; O'Malley, *Beng. Dist. Gaz.*, 1906, i., 49, 54; ii., 80-1; iii., 109; *Repts. Dept. Land Rec. and Agri. Beng.*; *Dumraon and Sibpur Exper. Farm Repts.*]

Eastern Bengal and Assa.—Wheat is a very unimportant crop in Assam. The area returned for 1904-5 was 10,012 acres, practically the whole being in Goalpara. The *Final Memorandum* on the crop for 1906-7 states the area and yield in the new province of Eastern Bengal and Assam to have been in 1905-6, 159,800 acres and 50,000 tons; and in 1906-7, 168,700 acres and 44,000 tons. Cultivation in Assam as yet is almost entirely of an experimental nature. An account (*Rept. Dept. Land Rec. and Agri.*, 1904, 20-1) of some of the experiments made in 1903-4 in Manipur and certain localities in Cachar and the Assam Valley is given. "In Manipur," it is stated, "one of the four experiments made gave a very successful result, the yield being no less than 2,140 lb. of grain to the acre," but in the other localities they generally proved a failure. Summarising the experiments, it is said that "wheat will undoubtedly thrive and give a good yield in Manipur; it promises well in the Naga hills, but the people need to be educated to appreciate and tend the unaccustomed crop. The same remark applies to Nowgong and Kamrup, and there is a fair prospect of success with wheat in these two districts."

Pro es well.

The area in Eastern Bengal does not usually much exceed 150,000 acres. Taking Eastern Bengal and Assam together, they may be said normally to possess a wheat area equivalent to 1 per cent. of the total wheat area of British India.

Madras and Mysore.—Wheat is unimportant in the Madras Presidency, and occupied only 15,276 acres in 1905-6. In Mysore the corresponding area was 1,178 acres, and according to the *Final Memorandum* there were in 1906-7, 4,600 acres. The largest tracts are in Karnul, Bellary, Kistna, Guntur, Cuddapah, the Nilgiris, Anantapur and Madura. In Mysore, Chitaldrug and Shimoga are the most important districts. A brief statement of Mysore is given in the local *Gazetteer* (1897, i., 129-30) by B. L. Rice, compiled largely from Buchanan-Hamilton. Two kinds are said to be cultivated, *jave godhi* (affirmed to be *T. monococcum*) and *hotte godhi* (*T. Spelta*). Rice tells us that in Kolar *jave godhi* (whatever species it may be botanically) is sown broadcast in May-June, after frequent ploughing, and the crop ripens in three months. In the black clay of Madgiri, *jave godhi* is also the most common crop. In Sira, when there is a scarcity of water, both *jave* and *hotte* are sown on rice-lands. A small quantity of *jave godhi* is raised near Periyapatna on fields of a very rich soil, from which alternate crops of *kadale* (*Cicer arietinum*) and of wheat are taken. Near Narsipur *hotte godhi* is grown, and there are two seasons for its cultivation, known as *hain* and *kar*. When the rains

adras
and
Mysore.

Districts.

Two Kinds.

S ons.

Rotation.

Yield.

set in early, the *kar* season is preferred, because the wheat is more productive and it may be followed by cotton. When the rains are late, the *kain* wheat is taken after *kadale*. The cultivation is the same as for the *kar* crop, only the season is different. In the *hain* crop the produce is said to be only about one-half of the *kar* crop (*Mysore Gaz.*, l.c.).

Burma.
Districts.

Bur a.—The area in 1905–6 was 35,178 acres, all in Upper Burma. The most important district is Sagaing, which had 24,361 acres in the year in question, while smaller areas are found in Kyauksé, Minbu, Mandalay and Lower Chindwin. The subject of wheat cultivation in the Southern Shan States and in Burma is fully discussed by a writer in *Capital* (Sept. 20, 1906, 587–8; Oct. 18, 749–50), who affords much useful and practical information which deserves careful consideration. He there states that “experimental cultivation with the object of ascertaining whether wheat could be grown as a staple crop was begun as early as 1888–9, and the results tend to show that this crop can be successfully grown in the Upper Chindwin district, the Pyinmana Sub-division of the Yamethin district, in Magwe, Maymyo and in the Chin hills. Wheat also succeeded on the river silts in the Toungoo district in Lower Burma, but the outturn was in every case poor.”

Southern Shan
States.

The efforts made by A. H. Hildebrand to establish wheat cultivation in the Southern Shan States have been repeatedly told in official publications (*Repts. Dept. Land Rec. and Agri. Burma*).

Outturn.

The *Agricultural Statistics* give the average outturn of wheat in Burma, for a period of five years ending 1901–2, as 635 lb. for the province as a whole. Separate returns are shown for Mandalay, Sagaing, Minbu and Kyaukse, and these range from 320 lb. in Mandalay to 800 lb. in Minbu. It has sometimes been affirmed that Burma was to India a great granary. It certainly produces an immense amount of rice, which is mainly exported but of course is available should India require it. That it could similarly afford a large supply of wheat may very possibly be found to turn more largely on the deficiency of labour supply than on defective climate and soil.

illin .

Baking.

MANUFACTURES.—For the minor uses of wheat straw see p. 116. Very little can be recorded regarding the indigenous industries of milling wheat and producing flour. Loaf-bread (p. 1109) is now produced in the larger villages and towns, and in some few localities (such as around Delhi) the baking of biscuits, specially designed to meet the growing demand for imported goods of that nature, seems to be fairly successful and to give promise of a great future. In other parts of India, as for example the towns of Gujarat, the manufacture of macaroni is well understood and fairly largely practised. The use of flour in the production of certain sweetmeats has originated a demand for the commodity. In the Panjáb, as already mentioned, wheat becomes the staple food and is consumed in the form of large cakes cooked over the open fire. All over India, therefore, the *chakkwala* or grinder may be met with plying his craft, either by employing women to work the ordinary hand-mill (*chakki*) or, where a fall in the water-level can be obtained (as for example on the hills), by using the water-driven flour mill. But in addition to such indigenous methods, within the past twenty years or so flour mills after the most improved European fashion have been established and very superior flour may now be procured everywhere, and of such quality as to have checked the imports

M roni.

FLOUR MILLS

of the foreign article. In a further paragraph, particulars will be found of the imports and exports of flour, but it may be added that the growth of the Indian flour traffic is one of the most encouraging indications of the birth of industrial enterprise. So far, the exports of Indian flour have gone to Indian Ocean ports, but the day is perhaps not far distant when the problem of the exports of clean *versus* adulterated wheat may be solved, as already stated, by the export of flour (see p. 1089).

Flour Trade.

Flour Mills.—According to the *Financial and Commercial Statistics* (1906, 399) there were 42 mills, employing 3,016 persons in 1904, but the statement is said to be defective. These were distributed thus:—The Panjáb 21, with 1,281 employees; Bengal 9, with 755 employees; Bombay 4, with 562 employees; United Provinces 4, with 273 employees; Madras 2, with 58 employees; Sind and the Central Provinces, 1 each, with 52 and 35 employees respectively.

Flour Mills.

INDIAN TRADE IN WHEAT AND FLOUR.

For many years it was an accepted belief that Indian wheat appeared on the markets of Europe chiefly in order to supplement deficiencies. In 1899, the author of *The Wheat Problem* (Sir William Crookes) practically excluded India from consideration in his study of the world's supply, on the ground of the insignificance of the surplus available for export. In a most emphatic manner that view has been disproved by recent returns. In 1904, for example, India actually headed the list of countries that contribute towards England's demands—a circumstance that at once placed it in an altogether new position, notwithstanding that the very next year it fell far short of its record. But what it did one year may be repeated and even exceeded. The explanation of this new state of affairs may be learned from a study of the causes that have brought about India's extended wheat production. Nearly 75 per cent. of the wheat grown is raised in the Panjáb and the United Provinces. And in these provinces vast tracts of fertile land have been brought under cultivation, through the improved and increased canal and well irrigation accomplished by the Indian Government. Indeed fully half the wheat area of the provinces named is ordinarily under irrigation wheat. Howard (*Note Prod. of Wheat, in Agri. Journ. Ind., 1906, i., pt. iv., 399–401*) regards the irrigation wheat as securing the internal consumption and as thus releasing a large proportion of the dry crop for export. The expansion of the irrigation wheat area is, therefore, a matter of superlative importance to the British Empire, in addition to being of vital interest to India itself.

Increased Canals.

Expansion of Irrigation Wheat.

Vital to India.

Prices of Wheat in India.—These are expressed by the number of seers (= 2 lb.) procurable for Rs. 1 (= 1s. 4d.). A higher figure, therefore, denotes cheap wheat (more being obtainable), and a low figure dear wheat. It is perhaps only necessary to select three centres, Calcutta, Bombay and Delhi, to exemplify the fluctuations in price. During the twenty years ending 1905, the cheapest wheat in Calcutta was in 1887, when 14·17 seers (28·34 lb.) were obtained for the rupee. So again the dearest wheat was in 1897, when only 8·05 seers were given. The quantities procurable for the past four years were 1902, 10·68 seers; 1903, 12·1 seers; 1904, 11·42 seers; and 1905, 10·67 seers. In Bombay, the record year for cheapness during the twenty years was in 1896, when wheat sold at 11·84 seers to the rupee, and the dearest year 1900, 6·06 seers, while for the following years

India.

it sold at—1902, 7·37 seers; 1903, 8·12 seers; 1904, 8·31 seers; and 1905, 8·33 seers. Wheat in Bombay during the term of years mentioned has manifested much more violent fluctuations than in Calcutta. Thus in 1895 it sold at 13·18 seers, and in 1897 at 6·66 seers. In Delhi, wheat is naturally very much cheaper than in either Calcutta or Bombay; and its record years were, for cheapness 1885, 22·5 seers, and for dearness 1897, 9·91 seers to the rupee, while during the last four years ending 1905 the prices were—1902, 15·14 seers; 1903, 15·26 seers; 1904, 15·0 seers; and 1905, 12·95 seers. The price in Delhi is representative of all towns within the wheat-producing areas, such as Lahore, Lucknow, Cawnpore, Raipur, Patna, etc. A careful scrutiny of the returns of the wheat production and trade for India gives no sort of justification for the opinion that the exports to foreign countries are raising the price of wheat to the people of India, while on the contrary the annually increasing surplus has even now assumed the position of a valuable safeguard against famine.

PRODUCTION AND EXPORT TRADE OF WHEAT.—The wheat exports of one year are very nearly entirely drawn from the area of production of the year previous. Similarly it is often the case that the area of production in the British provinces is spoken of as that from which the foreign exports are drawn, thus neglecting the Native States, which undoubtedly contribute considerably to the amounts shown as exported. A mean average yield per acre for all India would be a perfectly misleading figure, since the range between irrigated manured land and dry land without manure (without taking into consideration the difference in yield between pure and mixed crops) would be perhaps three of the former to one of the latter. But accepting the official returns as they stand, we obtain an average for the ten years ending 1905–6 of 24,299,149 acres, with a yield of 7,170,551 tons (or 143,411,020 cwt.) of grain, while the actual figures for 1905–6 were 26,226,200 acres and a yield of 8,560,340 tons (or 171,200,000 cwt.). The decennial average is perhaps the safer figure to employ in all comparisons, since it is considerably below the actuals for the past few years and errs on the side of under- rather than over-stating production. It would, however, serve no useful purpose to strike averages for the exports from India, since these are open to none of the errors mentioned. The following abstract table exhibits the exports from India for the years 1902–7, and contrasts these with the chief items of wheat imports into Great Britain :—

Canada ..	9,527,475	10,802,127	6,195,300	6,522,030	11,309,700

The table exhibits many instructive features, some of which may be here dealt with. For example, of the exports from India by far the most important purchasing country is the United Kingdom. The next important countries are—Belgium, France and Egypt. In 1905-6 these three together took 3,039,881 cwt., or little more than one-fifth of the supply consigned to the United Kingdom alone. And what is perhaps even more significant, the demands of all countries (other than Great Britain) have practically remained stationary for some years past, while the supply to the United Kingdom has gone forward in a most significant manner. So also the figures of shares taken by the ports of shipment from India exhibit a remarkable parallelism with recent extensions in irrigation and facilities in transport. The port of Karachi taps the Panjáb, Rajputana and to some extent also Central India and the United Provinces. The expansion of the Karachi traffic has been phenomenal, and the extension of railway communication toward Calcutta must to some extent account for the progress made by that port.

United Kingdom.

Singular Progression.

Karachi the Chief Port.

Reverting to the decennial standard, it may now be shown what proportion the exports bear to production. The average production of the ten years ending 1905-6 has been shown as 143,411,020 cwt. The exports from India in 1905-6 came to 18,750,467 cwt. (valued at Rs. 8,53,43,996), or 13 per cent. on the average standard; but if the figure of actual production for the year named be accepted, viz. 171,206,800 cwt., the exports would represent only 10·9 per cent. of the supply. The year 1903-4, as also 1904-5, was notable in the wheat trade. India exported in the former 25,911,312 cwt. (valued at Rs. 11,08,89,546), which expressed to the decennial standard would be 18 per cent., and to the actual crop of 1903-4 13·4 per cent. In 1904-5 the exports were 43,000,502 cwt. (valued at Rs. 17,90,60,692 or £11,937,379), or 30 per cent. on the decennial standard and 28·2 per cent. to the recorded actual production.

Exports versus Production.

Percentages.

An examination of the table given reveals the further fact that in 1904-5 India headed the list of countries concerned in the supply of wheat to Great Britain. In that year it furnished the United Kingdom with wheat valued at close on 8 million pounds sterling. India's contribution was then close on 29 million cwt., while Russia supplied 23½, the Argentine 21½, Australia 10, the United States 7, and Canada 6 million cwt.

India's Contribution.

PRODUCTION AND TRADE IN FLOUR.—The proportion of flour exported from India gives, of course, no evidence of the magnitude of the

Flour.

total production. There would seem little doubt, moreover, that by far the major portion of the flour annually produced in India is turned out by the indigenous hand- and water-power mills and thus escapes registration of any sort. No more particulars can, therefore, be afforded of the consumption of flour than are implied by the annual production of wheat and the balance of that cereal that remains in the country over and above the foreign exports.

Balance over

Karachi.

Exports of Flour.—There is, however, a considerable trade in exporting wheat flour, and this has manifested recently a noteworthy expansion, although the traffic of last year showed a decline from the returns of the years immediately previous. In 1900–1 the exports were 497,346 cwt., valued at Rs. 35,83,176; 1901–2, 529,328 cwt., valued at Rs. 37,12,876; 1902–3, 718,077 cwt., valued at Rs. 46,54,631; 1903–4, 810,422 cwt., valued at Rs. 52,98,843; 1904–5, 1,031,495 cwt., valued at Rs. 69,21,610; 1905–6, 899,056 cwt., valued at Rs. 63,83,264; and 1906–7, 818,462 cwt., valued at Rs. 58,57,116. The great bulk of these exports goes from Bombay, viz. 661,368 cwt. in 1906–7, the balance being divided between Bengal and Sind, while the chief markets are Arabia, Aden, Ceylon, Mauritius, British East Africa, the Straits Settlements and Egypt. A considerable export trade in wheat flour to the United Kingdom appeared for the first time in 1904–5, amounting to 52,523 cwt., but contracted to 1,800 cwt. in 1906–7.

I ports of Wheat and Flour.—A certain amount of foreign WHEAT is imported into India, and according to Noël-Paton (*Rev. Trade Ind.*, 1906, 31), “in times of shortage it is taken in considerable quantities even by ports from which grain is commonly shipped.” The quantities have been:—1902–3, 783 cwt., valued at Rs. 4,757; 1903–4, 18,852 cwt., valued at Rs. 97,764; 1904–5, 129 cwt., valued at Rs. 432; 1905–6, 454,614 cwt., valued at Rs. 22,53,648; and 1906–7, 209,696 cwt., valued at Rs. 11,38,976. Of the total for 1905–6, Australia supplied 395,696 cwt. and Turkey-in-Asia 58,798 cwt. Noël-Paton points out that “this total was exceeded only in 1896–7 and in 1900–1, when 601,356 cwt. and 559,351 cwt. respectively were imported; but in each of the famine years, 1877–8 and 1878–9, the imports exceeded 400,000 cwt.” Small quantities of wheat flour, subject to duty, are also imported, and have averaged for the years 1902–7, 18,500 cwt.

Internal Traffic.—Rail and Riverborne Traffic.—The total transactions by these routes on the average for the years 1902–7 were 31,874,712 cwt. wheat and 1,699,091 cwt. flour. In 1906–7 the figures were 28,556,137 cwt. wheat and 2,350,388 cwt. flour. Of wheat, the Panjáb exported that year 20,537,369 cwt., viz. to Karachi, 14,959,915 cwt.; to Rajputana and Central India, 1,594,477 cwt.; to Calcutta, 1,217,100 cwt.; to the United Provinces, 1,119,578 cwt.; and to Bombay, 1,025,751 cwt. It will thus be seen that the bulk of the railborne traffic is from the Panjáb to Karachi. But Karachi obtains wheat also from Sind province and from the United Provinces, the grand total of its supplies having been in the year under notice 17,018,238 cwt., an amount which it will be seen would have sufficed to meet the foreign exports of 15,434,060 cwt. Of course it is not always safe to assume that the actual amounts shown in the internal traffic appear again in the foreign transactions, but the average of several years would overcome the overlappings that take place. It is sufficient, therefore, to show that the wheat exported from Karachi to foreign countries is drawn mainly from the Panjáb.

THE WHITE DAMMAR TREE

After the Panjáb come the United Provinces; in 1906-7 these consigned by rail 2,982,862 cwt., of which Calcutta took 1,812,924 cwt. Next come the provinces of Sind and Baluchistan, which exported during the year in question 2,085,224 cwt., almost entirely to Karachi. Lastly, the Central Provinces and Berar supplied 1,683,046 cwt., of which Bombay took 494,405 cwt., Calcutta 299,686 cwt., while the United Provinces drew 418,108 cwt., and Rajputana 267,333 cwt. The total receipts by rail at Calcutta came to 3,407,430 cwt., at Bombay 1,749,615 cwt., quantities that allow for a large local consumption and still leave a balance sufficient to meet their foreign exports. The local consumption of Calcutta and Bombay, unlike that of Karachi, is more important than the foreign exports.

The railborne traffic in flour is from Calcutta 759,586 cwt., to Bengal province and Assam; from the Panjáb 802,423 cwt., to the United Provinces, Bengal and Calcutta; from the United Provinces 314,101 cwt., to Bengal and Calcutta; and lastly, from Bombay (port) 292,154 cwt., to Bombay Presidency, Mysore and the Nizam's Territory.

Coastwise Traffic.—The traffic by this route is not as a rule very extensive. For the period 1901-6 it averaged 1,321,912 cwt. wheat, valued at Rs. 64,75,711, and 462,681 cwt. flour, valued at Rs. 32,28,418. The exports are mainly from Sind to Bombay, Kach and Kathiawar; from Bombay to Kathiawar and Madras; from Bengal to Madras; and from Burma to Bombay and Madras. The corresponding traffic in flour is largely to Burma, and from Bombay to Madras and Burma. [*Cf. Twenty Years' Wheat Imports, in Journ. Board Agri., 1904, xi., 534-42.*]

V

VAT IA I ICA, Linn.; *Fl. Br. Ind.*, i., 313; Gamble, *Man. Ind. Timbs.*, 1902, 85-6; Talbot, *List Trees, etc.*, 1902, 35; Cooke, *Fl. Pres. Bomb.*, 1903, i., 86-7; Brandis, *Ind. Trees*, 1906, 72-3; **DIPTEROCARPEÆ**. The White Dammar of South India, Piney Varnish, Indian Copal or Malabar Tallow, *saféd damar, kahruba, sandras, rál, vellai-kunrikam, painipishin, kungliyam, piney maram, gugh, dupa maram, dhupada, payani*, etc. A large evergreen of the forests at the foot of the Western Ghats from Kanara to Travancore, ascending to 4,000 feet, often planted as an avenue tree.

This tree yields a true RESIN of considerable value known as White Dammar or Piney. It is said to occur in three forms—compact piney, cellular piney and dark-coloured piney resin. The names sufficiently indicate their respective characters, which are said to be due to the mode of collection and the age of the tree. The resin is obtained in the usual way by incising the trunk. It is only slightly soluble in alcohol, but dissolves at once in turpentine and drying oils, and, like copal, is chiefly used for making VARNISHES. It has been recommended for use in pharmacy in place of the officinal pine resin. Gamble states on the authority of Mr. J. H. Brougham that in certain localities the resin is mixed with cocoanut oil and rolled into candles. The Natives also employ it to make imitation amber beads. The seeds contain a large quantity of a solid OIL known as "piney tallow," or vegetable butter of Kanara. In South Kanara this is used for lamps, for flavouring food, as a substitute or adulterant for ghi, well as for medicinal purposes. According to Bidie, it is valued locally an application in rheumatism. It has been employed in the manufacture of candles, which were at one time introduced into England. Hooper (*Agri. Ledg.*, 1902, No. 1, 16) states that a sample of the fruit was found to contain 25 per cent. *Jannin*. The bark is also very astringent. Bourdillon (*Notes on Trees in Travancore*, 30-1) says that it is used in Ceylon to keep toddy from fermenting. Hooper

The khas-khas or Vetiver; the *khas*, *bená*, *panni*, *balé-ká-gháns*, *shanadér jhar*, *sirom*, *tin*, *válo*, *vettí-vér*, *lávanchá*, etc., etc. Is found throughout the plains and lower hills of India, Burma and Ceylon, up to 4,000 feet, occurring on moist, heavy soils, more especially the margins of lakes or streams.

Fibre.

The root or *khas-khas* is extensively made into the aromatic scented mats which are hung in doorways and kept wet to cool the atmosphere during the hot season. It is also used for making fans, ornamental baskets, etc., which are very largely produced at Savantvadi, Poona, Chanda and elsewhere. The raw material is exported to Europe chiefly from Madras ports. Gildemeister and Hoffmann (*Volatile Oils*, 289) say, "The root is of a reddish colour and often contaminated with red sand. A half-distilled root is frequently found in commerce, and can be recognised by its light colour." It seems more than probable that much of the so-called half-distilled root is in reality the roots that have been used in *tatties* for a season and are bought back by the traders to be exported. The constant application of water and exposure to the fierce sun might easily exhaust a large proportion of the oil and bleach the roots in the manner described. According to certain inscriptions, taxes were levied on *khas-khas* in 1103 to 1174 A.D. (*As. Soc. Beng.*, 1873, 161). The roots when distilled with water yield a fragrant OIL (known in European trade as *Vetiver*, which is used as a perfume and for flavouring sherbet. It commands a high price in Europe, being employed in many favourite scents. It is the most viscid of essential oils, and hence its sparing volatility is taken advantage of in fixing other perfumes. The oil is hardly, if ever, exported from India, European supplies being either locally made from the Indian roots or derived from Réunion. According to Piesse, the yield is about 10 oz. per cwt.; other observers have found it to vary from 0.2 to 3.5 per cent. Rheede, who was perhaps the first European author to allude to this plant, calls it *ramacciam*, and says that with the Brahmins it was *bocalo*. It was in his time both wild and cultivated in Malabar on account of its roots, which were used medicinally.

Red- and White-
coloured Roots.

Oil.

Vehicle of
Other Perfumes.

Medicine.

In MEDICINE the root has been regarded by European physicians as a dia-phoretic and as a preservative against cholera (Pereira, *Mat. Med.*, ii., pt. i., 132). In *The Bower Manuscript* (which appears to date from the 5th century) frequent mention is made of *usira* or *virana*, which Hoernle renders as the present odoriferous grass; it was an ingredient of a plaster beneficial to the complexion. A pte is rubbed on the skin to relieve excessive heat; an aromatic cooling bath is made by adding to a tub of water a powder of the root with that of *Pavonia odorata* (red sandal-wood), and the wood of *Prunus Puddum*. The grass (leaves, etc.) is suitable for paper-making, and it is said that 60,000 to 70,000 maunds are annually available in the Hissar district of the Panjáb alone. When young, the grass affords good FODDER, and is also in universal demand for thatching purposes. [Cf. Taleef Shereef (Playfair, transl.), 1833, 14; Taylor, *Topog. and Stat. Dacca*, 1840, 57; Hoey, *Monog. Trade and Manuf. N. Ind.*, 1880, 160; *Journ. Ind. Art.*, 1884, i., No. 3, 7; Duthie, *Fodd. Grass. N. Ind.*, 1888, 37; Gee, *Monog. 1904, 178; LEGUMINOSÆ. The Garden Bean, *bákla*, *anhuri*, *nákshan*, *kálin*, *chastang raiün*, *sein*, etc. De Candolle considers its introduction into India to be quite recent, though this would seem to be true only of the plains. In the higher Himalaya it is not unlikely that its cultivation has passed down from the most ancient times.

At the present day it is cultivated in the plains here and there in European gardens, and chiefly in the United Provinces. There are two distinct forms, the long-podded and the broad-podded, the latter originating the name "Broad" or "Windsor bean." The former is said to succeed best in India, though Firminger recommends the "broad bean" for garden cultivation. The seed should be sown about the middle of October, and previous to sowing should be steeped in a basin of hot water for twelve hours or more. [Cf. Bentham, *Rev. of Targioni-Tozzetti*, in *Journ. Hort. Soc.*, 1855, ix., 138; De Candolle, *Orig. Cult. Plants*, 1884, 316; Church, *Food-Grains of Ind.*, 1886, 132; Asa Gray, *Scient. Papers*, 1889, i., 349; *Pharmacog. Cow Pea.

Variety.

It has been pointed out, under *Dolichos Lablab* (p. 508), that the name *lobiá* (lobos of the Greeks) is commonly applied to that plant and loosely by Indian market gardeners to any pulse, but more especially denotes the present plant. The word *lobiyá* may be, however, derived from the Sanskrit *lobhya* (=alluring); it occurs among the list of autumn (*kharif*) crops known to Akbar, and since *Vigna Catjang* comes into season in the autumn it is probably the plant referred to. The crop, as a rule, is grown in fields for its seed, and used as a pulse. It may be cultivated alone, but is generally a subordinate crop. Various races exist, one of which, with long pods, is raised by market gardeners as a vegetable and sold as a substitute for French beans.

Names.

CULTIVATION.—In Cuttack Bengal, where it is cultivated alone, Banerjee (*Agri. Cuttack*, 1893, 81-2) states that "it is grown on high loamy lands, and in rotation generally follows *biali* and *mandia*." The soil is prepared and the seed sown broadcast in September-October. In December-January, when thoroughly mature, the plants are plucked up by the root. "The variety raised for vegetables begins to yield fruit in November-December." Basu remarks that in Lohardaga it is "always grown as a second crop along with *máruá* (*Eleusine coracana*) and occasionally with *gorá* or upland paddy." In July the seed "is thinly scattered over the fields at the rate of 1½ seers per acre. The pods when they ripen are hand-picked at the same time, or just before harvesting *máruá*. The average outturn is one maund per acre, the heaviest yield never exceeding 2 maunds; the value of the produce is about Rs. 1-8 in a year of ordinary prices."

Special Race.

Cultiva-
tion:
engal.
Rotation.
Season.

Outturn.

In the United Provinces there were 1,062,783 acres under *úrd*, *múng*, *moth* and *lobiá* during 1904-5. Later figures are not available. "It is less frequently grown as a sole crop than either *múng* (*Phaseolus radiatus*) or *úrd* (*P. Mungo*), and the area which it occupies by itself is quite insignificant except in the Rohilkhand Division. On the other hand it constitutes a distinct feature of the undergrowth in a large proportion of *kharif* millet and cotton fields, with which it is associated at the commencement of the rains. It ripens in October or November, and yields a produce of about the same quantity as that of *úrd*" (*Field and Garden Crops*, l.c.). In the *Season and Crop Report* for 1905-6 it is stated that the area under this pulse was 32,703 acres, of which 1,766 were raised in the *rabi*. With regard to Bombay, Mollison says "it is grown with other pulses subordinate to *báji* in light alluvial soils in the Kaira district. It does better in moderately light soil than in soils of heavier or denser consistence. It is

grown alone in the *kharif* season in garden lands to produce a green vegetable—the so-called French bean of India—and in the *rabi* season is grown like *mug* and *udid*, to a limited extent as a second crop in rice fields.”

The grain is eaten either as flour or split as *dāl*, and, as already mentioned, the green pods, especially of the long-podded form, are plucked while young and eaten as a vegetable. As a curiosity it may be mentioned that the stalks and leaves are said to be employed in the preparation of a green dye. [Cf. Church, *Food-Grains of Ind.*, 1886, 156; *Pharmacog. Ind.*, 1890, i., 489; Basu, *Agri. Lohardaga*, 1890, pt. i., 68–9; Gollan, *Ind. Veg. Garden*, 1892, 127; Duncan, *Dyes and Dyeing in Assam*, 1896; Burma, *Settl. Vinegar.

VIN GA (AC TU).—Vinegar is an acid liquid, used largely as a food auxiliary, as a preservative for certain articles of diet, as a medicine, and lastly for certain industrial purposes. It is produced by (a) what is known as acetous fermentation of a mixture of malted and unmalted grain (forming malt vinegar), and (b) the oxidation of white or red wine (yielding white or red wine vinegar). Chemically it is a dilute solution of acetic acid with certain organic substances derived from, and peculiar to, the material from which made. It is, in other words, a weak solution of acetic acid, produced by the fermentative action of a vegetable organism (*Mycoderma aceti*), the process of transference being called acetous fermentation.

Early Records.

History.—Mr. F. W. Thomas informs me that *śukta* is the most general Sanskrit name for the true or fermented liquor. This occurs in the *Brāhmaṇas*, *Suśruta* and elsewhere. *Sauktika* is an adjective form of the word met with in *Charaka* (1st century A.D.). It denotes very possibly the vinegar prepared from a sweet liquid, such as sugar-cane juice, palm-juice, etc. But malted vinegar seems also to have been understood, and is possibly denoted by the word *kāñjika* (sour or fermented), rice gruel (see the account under Burma, p. 1111). The *Bhāvaprākāśa* defines vinegar as a substance fermented from bulbs, roots, and fruits with oil and salt, and this use of oil and salt will be found frequently alluded to. The *Rājanirghanta* alludes to the employment of grain in the production of *cukra*. Lastly, *cukra* or *cukra* is applied to sour substances (such as the fruits of the tamarind and the sorrel) which are used as substitutes for vinegar. These occur in *Suśruta*, *Harivamsa*, etc.

Oil.

Salt.

Vinegar is known all over India by its Hindustani name *sirka*. In the provinces the following vernacular names are given to it:—*kadi* in Tamil; *pulla nilla* in Telugu; *chuka* in Malayan; and *pon-ye* in Burmese. While thus doubtless a substance of universal knowledge to-day and one which bears a fairly ancient record, it is significant that most works on India, both ancient and modern, have remarkably little to say about it. Writers on *Materia Medica*, as well as most of the standard authors on travel, etc., in India, are silent regarding vinegar. Even the *Institutes of Manu* makes apparently no reference to it. With the Muhammadans, however, vinegar always has been a more important dietetic luxury than with the Hindus, and to this circumstance perhaps is due the scant attention paid to it by early writers. It is, however, alluded to by Thevenot (*Travels in Levant, Indostan, etc.*, 1687, pt. iii., 16) and one or two other European travellers.

Standard
Authors.

PROVINCIAL PRODUCTION

VI GA
en al and
United Provinces
ource.

MANUFACTURE.—Most of the Indian vinegars are prepared from sweet liquids derived from palm-juice, sugar-cane juice, crude sugar, honey, *mahua* flowers, grapes, raisins, and other fruits. They are thus not malted, though of course fermented and mostly by the slow process. Each kind of vinegar is named after the substance from which it is produced; thus *tári-ká-sírka* would be the vinegar of toddy, etc.

Bengal.—N. C. Chaudhury, Travelling Inspector, Department of Agriculture, writes that in Calcutta there are some twelve shops where *sherka* (*sírka*) is manufactured. Each shop turns out about 300 maunds annually on the average. No *sherka* is imported into Calcutta from Bengal districts, though it is known to be prepared on a small scale in Bihar. It is made chiefly from cane-juice (see p. 952), but also from *gúr* (raw sugar), and occasionally from the fruits of the *jáman* (*Eugenia Jambolana*, see p. 526). The manufacture from cane-juice may be briefly indicated:—Cane-juice is kept in a big earthen pot (*jala*) (sunk in the ground up to the middle) in an open place and exposed to the sun. The mouth is covered with an earthen basin (*gamia*). The *jala* may contain 10 to 16 maunds of juice. Ordinarily it takes three or four months, sometimes six, to complete the operation. After a month or two, when fermentation has taken place briskly, the juice is transferred to a fresh *jala* till the fermentation is finished. The liquor (*sherka*) is then conveyed into smaller *jalas* and is thus ready for sale. Out of 40 seers of juice, 30 seers of *sherka* are obtained. In the case of *gúr* or date sugar—"to one maund of *gúr* or sugar, 4 to 5 maunds of water are added, and the solution thus prepared is treated just as with cane-juice. It takes a little longer time—say about fifteen days more—to finish the preparation of the vinegar from the materials named. Forty seers of the sugar or *gúr* solution yield about 34 or 35 seers of *sherka*. No special details are furnished regarding the production of vinegar from *jáman* fruits. Cane-juice *sherka* is sold at Rs. 5 per maund, the *gúr sherka* at Rs. 4, the sugar *sherka* at Rs. 4–8 per maund, and the *jáman sherka* at Rs. 12 per maund."

Price.

Eastern Bengal and Assam.—Information has been received from the Deputy Commissioner, Sylhet, and the Collector, Dacca. The former writes that vinegar is prepared on a very small scale and for home consumption only. It is made from the juice of (1) *bhubi* (? *Garcinia paniculata*, see p. 555), (2) blackberries (*Eugenia Jambolana*), (3) pine-apples (*Ananas sativa*, see p. 69), (4) *ámlaki* (*Phyllanthus Emblica*, see p. 887), and from that of sugar-cane and date-palm. The Collector, Dacca, states that in the town the vinegar sold is chiefly imported from abroad. "In Dacca there are only two firms who carry on the manufacture, and in both the business done is very small. The process is exceedingly simple. In one case the substances used are (1) the juice of the date (see p. 886) or palmyra palm (see p. 170), (2) bread (see p. 1100) and (3) gram (*Cicer arietinum*, see p. 300). The earthen jar is filled with date or palm juice, and then a few slices of bread and a few handfuls of gram are thrown into it. The mouth of the jar is closed with a cover, and the liquid allowed to ferment in that state for a month or six weeks or until the fermentation is complete. It is then passed through a clean cloth and put into bottles. The vinegar thus manufactured is sold at 2 or 3 annas per bottle." In the other manufacture the ingredients are (1) cane molasses, (2) putrid pine-apple and (3) gram, while the process of manufacture is exactly the same. The addition of bread and gram and the utilisation of the waste materials and wild pine-apples are interesting features of this special Eastern Bengal industry.

U. Prov.

United Provinces.—Hoey (*Monog. Trade and Manuf. N. Ind.*, 1880, 180–1) tells us that the chief material used in the manufacture of vinegar is *shíra* (see p. 952). "When sugar-cane is crushed it gives out the juice called *ras*. This is boiled and *gur* and *ráb* are made. The froth is skimmed off and put aside. The crushed stalks of the cane are laid in a vat (*haus*) with a small outlet below and the froth is thrown on them with a little water. The substance which comes trickling off is boiled and becomes *shíra*. This is the stuff which is purchased by the vinegar-makers and tobacco manufacturers" (see p. 807). In a long and highly interesting communication, the Assistant-Director of Agriculture in these provinces states that there are a great many substances employed in the preparation of vinegar, but that the liquor is chiefly obtained from cane-juice and cane-juice products. The other better known sources are palm toddy, grapes (see p. 1119), raisins, *jáman*, barley (see p. 643), etc. The methods of

Waste
Sugar-cane.

Sugar-juice.	manufacture are essentially similar to those already detailed in connection with the Lower Provinces. "Fresh cane-juice is obtained from the mills, strained through a piece of coarse cloth and filled into earthen vessels which have been well washed and dried for the purpose. The mouths of the vessels are then closed with stoppers to prevent foreign matter getting into them, and they are removed to a place of safety, where both sun and air can have free access. This naturally takes place at the beginning of the summer, towards the end of the crushing season, and the jars are allowed thus to stand till the commencement of the rains. Throughout the rains damp is avoided as much as possible, as it affects vinegar injuriously. The jars are placed in a dry and warm corner and exposed to the sun at intervals. If kept in a damp place, a thick scum develops upon the surface of the liquid—a mould which appears all in one piece. This bears different names in the localities of vinegar manufacture, the most common term for it is <i>sahri</i> . In Bijnore it is called <i>bilai</i> and in Meerut <i>bhadder</i> . The development of this mould is generally considered ruinous to the vinegar and the material is thrown away, but the more economical advocate curing it. They remove the scum carefully, filter the liquid, change the vessels and add various preparations consisting of <i>Chenopodium</i> (p. 293) seeds and chillies, or of asafetida (p. 535), garlic, chillies, and common salt. They also add raw <i>bel</i> (<i>Egle Marmelos</i> , see p. 28), <i>munj</i> (<i>Saccharum arundinaceum</i> , see p. 929), and a small quantity of sugar. If no attention be paid to the mould, the vinegar after some time altogether disappears."
Effects of Damp. Scum.	
Grape Vinegar.	Vinegar from toddy is said to be largely used for medicinal purposes, and sells at Rs. 10 to Rs. 12 a maund. Grape and raisin vinegar (see p. 1119) are more costly, selling at Rs. 15 to Rs. 20 a maund. Grape vinegar is thus described:—a solution is made of sugar in water, about 18 seers of sugar to a maund of water, and grapes are then crushed into this solution and the mixture set aside. In time it turns into vinegar. Being expensive, grapes are, however, not very largely used for this purpose on the plains. <i>Jaman</i> vinegar (see p. 526) is made chiefly in Lucknow and costs Rs. 10 a maund, while vinegar from barley costs Rs. 15 a maund. A highly refined form of vinegar termed <i>arak-náná</i> is obtained by redistilling ordinary vinegar along with a small quantity of mint (5 seers dry mint to the maund of vinegar). The substance is said to be extensively manufactured in Lucknow and to be used for pickling. It sells at Rs. 5 to Rs. 10 per maund.
Jáman Vinegar.	
Arak-náná.	
Panjáb.	The chief centres of the vinegar trade are stated to be the large towns and cities, notably Lucknow, Gorakhpur, Benares, Meerut, Bijnor, Agra and Shah-jahanpur. Lucknow prepares all sorts of vinegars, both edible and medicinal, and these are conveyed all over the Provinces and even to Calcutta.
Sugar-cane.	<i>Panjáb</i> .—In connection with the correspondence above indicated, communications were received from Lahore, Delhi, Multan, Jalandhar and Rawalpindi. Of Lahore, it is stated that vinegar is prepared in the usual way from sugar or sugar-cane juices (rarely from molasses), but in combination with grapes, with alum (<i>phitkari</i>), or with salt as adjuncts. The price per maund of one-year-old vinegar is Rs. 20, of vinegar six months old, Rs. 10. In Delhi there are four principal manufactories, and sugar-cane is almost solely employed. A maund of cane-juice gives 30 seers vinegar. The vinegar in greatest demand is <i>arak-naina</i> (or <i>-náná</i>) already described, namely that made from crude vinegar by adding mint and subsequently distilling the mixture. Vinegar is also occasionally made from grape-juice, raisins, <i>jamans</i> and oranges (see p. 327). The total output of vinegar in Delhi is estimated at 1,200 maunds a year. In Multan three kinds are made— <i>anguri</i> from grapes, <i>kishmash</i> from raisins, <i>jamani</i> from <i>jamans</i> , but it is prepared only in small quantities for local consumption.
Price.	The Deputy Commissioner of Jalandhar gives the method of preparation pursued there. To one maund of sifted <i>ras</i> (sugar-cane juice) are added five bottles of superior country vinegar and placed in a jar polished inside with <i>lakh</i> . The mouth is closed and the jar set on one side for three or four months. It is then filtered through a cloth at intervals "to rid it of worms or insects which collect in it." A quarter-seer of ground <i>tej pat</i> (<i>Cinnamomum Tamala</i> , see p. 313) leaves and half a <i>chittack</i> of ground <i>kaulanjí</i> (<i>Nigella sativa</i> , see p. 811) and chillies (see p. 268) are added, the mixture being left for a month or so more. It may now be ready for use. The vinegar prepared from cane-juice is reddish in colour, but this may be corrected by the addition of alum (see p. 61).
Arak-naina. Oranges. Grapes. Jaman.	
Alum.	In Rawalpindi district, according to Robertson (<i>Seilh. Rept.</i> , 1880–7, 1893, app., xxiv.), the manufacture of vinegar is a fairly important industry, the exports being carried by river from Attock to Sukkar. In the town of Rawalpindi only one vinegar-maker exists, who prepares it either from raisins (see p. 1114) or from <i>gúr</i> .
Raisins.	

A large earthen pot polished on the inside with goat's-grease is charged with one part raisins and four parts water, and the mouth closed as tight as may be and placed "in a room where there is little air, since there is a possibility of its being spoiled otherwise. After twenty days a *tola* of Peshawari salt and a *tola* of mercury in the ratio of a seer of raisins used, is mixed with it and the mouth of the vessel is again sealed. Twenty days after this operation the vinegar is ready for use (*i.e.* in forty days) and is then filtered and kept either in bottles or jars." Price Rs. 2-8, or 3s. per maund.

Salt.
Mercury.

Central Provinces.—Very little vinegar is made in these provinces. In a communication from Seoni it is observed, "The vendors of vinegar, and the confectioners who use it, in making up chutnies and other preserves, procure their stock from outside: from Nagpur, Jabbalpur and even from Delhi. The Deputy Commissioner of Betul speaks of a small manufacture from sugar-cane juice, as also from the berries of the *jáman* tree (*Eugenia Jambolana*). The berries are placed in an earthen jar along with some common salt and left for a few days. The juice is then squeezed out and placed in the sun for a short time. Mr. Sadasheo Narain of Gadarwara describes three forms of vinegar as prepared from sugar-cane juice, from *jaman* fruits and from raw sugar."

C. Prov.

Sugar.
Jáman.

Madras.—In the series of *Official Papers* mentioned above, a report issued by the Board of Trade, Madras, gives the particulars regarding that Presidency. The producers are the toddy-shopkeepers, and they convert their unspent toddy into vinegar in either of the following ways. The toddy is placed in a closed earthen pot and kept there till fermentation is complete and the liquid has become sour. The pot is either kept above ground for a month or two, or is buried underground for three or four months or more, and then taken out. The longer the pot is kept closed and underground, the better the quality of the vinegar. In either case pure vinegar is obtained when the pot is opened and the sediment has been removed. Vinegar is also made by heating fermented toddy either by fire or by exposure to the sun. It is procured in a shorter time by this method, but the quantity is less than by the slow or natural fermentation. The vinegar thus obtained is, however, used both for medicinal purposes and in cooking. There is no shop or bazar in Madras where country-made vinegar is specially sold, and the trade is not so extensive as that in either English or German vinegar (see p. 170).

Toddy.

Burma.—The information procured from the various districts show two main classes of vinegar as made, namely, from grain or from sweet fluids. The substances chiefly used in the manufacture are rice, peas, toddy, jaggery, sugar, dates and plantains. The observations regarding the preparation of vinegar from rice and peas are interesting, and amplify the Indian knowledge already exemplified. The rice (see pp. 826, 840) is boiled and then cooled for about three hours; it is then mixed with *congí* or water obtained from previously boiled rice. The mixture is then put into a pot of clean water and kept for three days in the shade. Some salt is now added (1 *tola* to 1 *viss* of liquor). The liquid may be seen to have turned slightly green and to have become sour. This is called *san-pon-ye*, and may be described as the domestic vinegar of the province. It is a crudely formed malt vinegar.

Grain.

Sweet Fluids.

Rice.

Salt.

With the peas (see p. 903) the process is similar. They are boiled till they turn soft and the water becomes reddish. This is strained off and put into another pot or jar, the mouth of which is tied up with a cloth. The fluid is boiled again, salt (3 *tolas* to 1 *viss*) added, and the boiling continued till the fluid is reduced by one-third, the result being crude vinegar. Speaking of the manufacture of vinegar from sweet fluids such as palm wine (toddy), mention is repeatedly made by the Burmese correspondents of the advantage of adding a few slices of bread so as to facilitate fermentation. In Mergui, vinegar of local manufacture is largely employed in preserving fish. It is prepared from stale toddy, chiefly the produce of the Nipa palm. Vinegar is said to be improved by placing a hot brick in it.

Peas.

Bread.
Toddy.

Trade.—There is no export trade in vinegar from India, and imports of vinegar, together with pickles, sauces and condiments, were recorded in the *Official Returns* for the first time in 1905-6, when the total quantity received amounted to 14,878 cwt., valued at Rs. 4,13,653; and in 1906-7, 16,300 cwt., valued at Rs. 4,77,033. The bulk of this import traffic is shown to come from the United Kingdom.

Wild
Grapes.

The Grape Vine is said to be indigenous in the temperate regions of Western Asia, Southern Europe, Algeria and Morocco (De Candolle). According to the *Flora of British India* (i., 652) it is "perhaps wild in the North-West Himalaya; cultivated extensively in North-West India, rarely in the Peninsula and Ceylon." Gamble (*l.c.* 190) says, "Has been introduced and successfully cultivated in Kashmir and other parts of India." Lawrence (*Valley of Kashmir*, 351) remarks that in the old days Kashmir was famous for its grapes, but now, if a few vineyards at the mouth of the Sind Valley be excluded, it is difficult to obtain a good dessert grape in the country." "Everywhere one sees giant vines climbing up poplars and other trees, but they are often wild, and their fruit is poor and tasteless."

istory.

istory.—Grapes have been known in India from a very remote period. In Sanskrit works the best-known names for the fruit are *drākshā* and *mṛidvikā*, while a spirit distilled from grapes (*maddhika*) is distinguished from that from sugar-cane, rice, barley, etc. As showing the antiquity of the knowledge in grapes, Dutt mentions that they are alluded to by Charaka and Susruta. Prior to the Muhammadan conquests of India we possess, however, no very precise information as to the cultivation of the grape in India proper.

Spirit.

Stein (*Ancient Khotan*, 1907, 448) tells us that while working in the ruins of Kara-Dong (8th century), he came across a cupful of "large black currants dried perfectly hard." In other passages (*l.c.* 253, 255) he invites consideration of the fact that in one of the paintings of Dandān-Uiliq, instead of the conventional fig-leaf, the vine-leaf had been substituted, and in still another passage (*l.c.* 245) he draws attention to the frescoes of Dandān-Uiliq, which manifest a vine-leaf and grape pattern. It is thus quite clear that the grape was well known at these early times, just beyond the north-western frontier of India. In *The Bower Manuscript* (Hoernle, transl., 1893-7), moreover, numerous references are found to the use of raisins in various medicinal preparations.

Vine-leaf
Designs.

Medi. e.

Ra.

But the medicinal uses of the vine recorded in Hindu literature are mostly concerned with the dried fruits or raisins and the spirit (*maddhika*), so that it is probable that prior to the Muhammadan conquests, both the fresh fruit and the various forms of raisins were, at the present day, imported from across the northern frontier. Many writers (Hehn, *Kulturpfl. und Haust.*, 1894, 65-94) have dwelt on the influence of the faith of Islam on vine-growing; the

East, seeing that the drinking of wine is contrary to Muhammadan law. Siraj-ul-Hasan (*Journ. Roy. Hort. Soc.*, xxix., n.s., 671-4; xxxii., 222-6) furnishes, however, many useful particulars regarding the vineyards of Daulatabad. These, he thinks, date from the time of Tagluq (1335 A.D.), but on Tagluq's death the capital was transferred to Delhi, and that event had a disastrous effect on the gardens. The following passages, perhaps, sufficiently indicate the Syed's views:—"During the time of the Bahmani Kings (1436 A.D.), Daulatabad became a military station under Parwiz-bin-Karanful. Once again the people began to pay attention to gardening, growing, however, only those kinds of vines that had survived the neglect of previous years." Then, in another passage, he remarks, "A great stimulus to grape cultivation was given by the Portuguese Christian Missions located at Aurangabad, which were liberally endowed by the early Bijapur or Ahmदनगर Kings in 1550. Their monasteries grew both purple and white grapes. Ibn Batuta, the Moorish traveller who visited Daulatabad in 1430, and the French traveller Thevenot, who made an extended tour in 1667, were much struck with the gardens that met their eyes throughout the Sarkar of Daulatabad." "This state of things continued till 1685 A.D., when Aurangabad became the capital of Aurangzeb. The city grew rapidly, and with it the demand for all sorts of luxuries." "In Daulatabad itself, the position for cultivating vines knew no bounds. Places of recreation provided by noblemen in their own gardens were entirely covered with vines. Even Fakirs looked upon the vine as a gift from Paradise, and had their mosques and monasteries adorned with it."

Indigenous Viticulture.

Kashmir.

Mysore.

The Emperor Baber (*Memoirs*, 1519 (Leyden and Erskine, transl.), 205) gives a full relation of the first occasion on which he tasted wine. His grandson Akbar, however, fostered and encouraged grape cultivation, and, by his direct aid, grapes of high merit were successfully acclimatised in the Panjāb and throughout the greater part of Northern and Western India. But on accession of Akbar's grandson the order went forth for the destruction of the vineries of Kashmir, and grape culture in India shared in the neglect that followed. The seventeenth and eighteenth centuries, therefore, witnessed a decline of interest in vine culture, sufficient to account for the low position the industry now occupies, and naturally the references either to the vine or to wine in the works of the early travellers are few, and mostly of a negative character. Nicolo Conti, who travelled in India early in the 15th century, speaking of a town called Panconia (supposed to be Pegu), says, "This is the only place in which vines are found, and here in very small quantity: for throughout all India there are no vines, neither is there any wine." This, doubtless, was not a very accurate statement, since shortly after other writers speak of grapes seen by them in various parts of India and Burma. Thus of Gujarat, Mandelslo (1638-40) says, "They want nothing but wine; but to supply their want of that, they have *Terri*, taken out of the *Cocos-tree*"; but Tavernier (1676) says that in Assam "There are quantities of vines and good grapes, but no wine, the grapes being merely dried to distil spirits from." Thevenot (*Travels in Levant, Indostan, etc.*, 1687, pt. iii., 16) tells us that the Dutch made wine from the grapes of Surat; and that in Golconda they made white wine (*l.c.* 104); also that wine-drinking was punished in Kandahār (*l.c.* 56). Ovington (1689) observes that Bannians, though they "are under restraint from the blood of the grape, yet will they freely taste the grapes themselves luxuriously with their juice, while it is innocent and harmless. We have grapes brought to Suratt, from the middle of February till towards the end of March; some from Amadavad, some from a village called Naapoure, four days' journey distant from Suratt." These would doubtless be described as the Deccan grapes of the Bombay shops to-day.

There is thus no doubt that large tracts of Upper and Western India are eminently suited for grape cultivation. Many quotations might be furnished to prove the extensive and diversified nature of the knowledge that exists in India and its chief frontier countries regarding the vine. Kanāwar, for example, is one of the Indian localities where what may be described as indigenous viticulture is a recognised industry, and Kashmir as an area of both acclimatised and wild grapes, so far as the present-day cultivation is concerned, and largely the trade in the produce of the vineyards of Afghanistan, Baluchistan and Kashmir is of no mean importance, and moreover capable of indefinite extension. To that category there seems every prospect in the near future of Mysore having to be added, namely an important centre of grape cultivation. [*Cf. Paulus Aegineta* (Adams, transl. and Comment), i., 172-8; iii., 271-3; Januensis,

According to Woodrow (*Gard. in Ind.*, 1903, 227), "The favourite varieties of grape that are grown in Europe have been introduced many times into India, but with few exceptions fail to become established." He then mentions the following forms as having been acclimatised and as being cultivated successfully in India generally:—White Mascadine (*safed angoor*); White Portugal (*Cashmeree* or White *Tokay*, *valayati angur*); Black Monukka (*bae-danae angur*); Black Hamburg (*hubshee angur*); and Faqira. Details regarding the methods of propagation, etc., as applicable to India, are given in detail in the same publication, but space does not permit of full treatment in this work. Perhaps one of the most important points to which attention should be paid, is the influence of atmospheric moisture. The fruit will not ripen when once the rains have broken, so that early maturity stock in direct adaptation to climatic conditions is essential. Firminger (*Man. Gard. Ind.*, 1904, 271) states that "the driest and hottest period of the year is when grapes ripen finest. This will be March in the Deccan, May in the vicinity of Calcutta, and June in the Upper Provinces."

Panjáb.—Henderson remarks that "in many parts of the Panjáb, the vine thrives quite as well as in Europe," and Baden-Powell (*Pb. Prod.*, 271) enumerates twelve different forms recognised there. Practically no information, however, is available regarding viticulture in recent years in the Panjáb. The reports of the experiments carried on at the Agri-Horticultural Gardens of Lahore contain little information, and are mostly a record of failure. While that is so, there are several very distinctive grapes regularly sold in the larger towns (such as the small seedless grape of the Delhi market) that seem well worthy of special study. Sly (*Agri. Journ. Ind.*, i., pt. iii., 268-9) discusses the fruit culture of the North-West Frontier Province. He says that 4,000 acres are under orchards, of which 2,700 are in Peshawar. He then discusses the grapes of Peshawar, Kohat, Kuram and Bannu. (For raisin Vinegar, see pp. 1110-1.)

Wines of Kashmir.—But the interest in Upper India centres very largely in the vineyards of the State of Kashmir. In the time of the Emperor Akbar, as already indicated, wine production was a very general industry, and held then a much more important place than at the present day. During the time of the Emperor Jahangir, the grapes of Kashmir were improved, but shortly after the decline set in which has been already alluded to. Coming down to modern times, the subject next assumed interest in 1876, when the late Maharajah Ranbir Singh took up the enterprise of vine-growing, and in 1885 had 352,525 plants in his various vineyards. At the Calcutta International Exhibition of 1884, red and white wines and also brandies made in Kashmir from the pure juice of the grape were exhibited, and obtained a gold medal and were highly commended for purity and excellence. This circumstance has often been overlooked, and the old tradition of India not producing wine been every now and

again commented on. It can and does produce wine, and no one can say that its wine industry of the future may not become one of its commercial triumphs. In spite, however, of the great expenditure lavished on them, the vineyards of Kashmir have not as yet proved the success anticipated, and in 1890 it became evident that the vines were suffering from *Phylloxera*. With reference to this, Lawrence (*Valley of Kashmir*, 1895, 351-2) states that "American vines were at once imported, and are now gradually replacing the unhealthy Bordeaux plants."

American Stock.

Commenting on the decline of the production of the eating grape, Lawrence observes that the people cut down their good vines in order to avoid the exactions of officials. "The grapes, white and red, from the State vineyard at Raipur in the Sind Valley are delicious, and efforts are being made to reproduce the Raipur vines in other parts of the valley. With the decline of the eating grapes, there has been an attempt to introduce the wine grape, and at present there are 389 acres of vineyards on the shore of the Dal Lake. The vines were introduced from the Bordeaux district." "Perhaps the vines of Burgundy would have been more suitable to Kashmir. Costly distillery plant was imported and set up at Gupkar on the Dal Lake, and wines of the Medoc and Barsac varieties, sometimes good, sometimes bad, have been manufactured year by year." "Besides the Medoc and Barsac, which are sold at Gupkar, a large amount of apple brandy is distilled and finds a ready sale." "The vineyards are under the direct management of the State, and, in spite of supervision, the vines do not receive the sedulous cultivation which alone can give success." "The business in present circumstances does not pay." [*Cf. Smythies, in Agri. Ledg.*, 1894, No. 15, 24-5, 27-8; *Coldstream, Vine Cult. in Kanawar*, in *Ind. Gard.*, Aug. 14, 1898; *Repts. Agri.-Hort. Gardens, Lahore.*]

Barsac.

Apple Brandy.

United Provinces.—Practically nothing of a definite nature has been written regarding grape cultivation in these provinces. The vine is said to fruit well in most districts throughout the plains, but the grapes are quite unsuited for wine manufacture. On the hills, however, it is otherwise, since at Kumaon, Kanáwar, etc., a fairly large industry exists in vine cultivation. In Kanáwar the vine has been cultivated since the early classic period, and several writers have spoken in high terms of the vines of Dehra Dun (*Ind. For.*, 1889, xv., 313-5). In the *Reports* of the Botanic Gardens at Saharanpur will be found some information regarding the experimental cultivation of foreign, mostly Afghan, varieties.

U. Prov.

Unsuited for
Wine.

Kanáwar.

"In Upper Kunawar," says Cleghorn (*Journ. Agri.-Hort. Soc. Ind.*, xiii., 382), "the vine is extensively cultivated and ripens its crop at an elevation of from 6,000 to 9,000 feet. The first plants are seen at Nachar, but the climate there is not suitable; beyond the Miru ridge which intercepts the heavy clouds, the smaller amount of rain favours the ripening of the grapes. The vineyards occupy sheltered situations, generally on the steep slope facing the river. The vines are supported on poles three or four feet from the ground, connected by horizontal ones. The fruit hangs below the shade of the leaves, never exposed to the sun. A considerable portion of the crop is dried on the house-top and stored as raisins for winter use, but without care, and many grapes are spoiled in the process. For several years the crop has been deficient, the grapes dropping off before they were ripe from unseasonable falls of rain and snow. This year, 1864, the rainfall was moderate, but the *Oidium* or vine disease appeared in the valley, and destroyed many vineyards. The fresh fruit is exported to Simla for sale in *kiltas* or large hill baskets, and the small seedless grapes dried are also sold there as 'fine Zante currants' at 2 rupees per pound. At Akpa and Poari the

6,000 to 9,000
Feet.

Oidium.

Lánang Grape.

price of fresh grapes is about one rupee for a *kilta*-full." "Sunnam is the highest point in the valley where the vine thrives."

In Kanáwar, says Mr. Atkinson (a later writer), the fruit is called *dakhang* and the plant *lánang*, and there the vine is extensively cultivated as a field crop, and ripens its fruits at an elevation of from 6,000 to 9,000 feet. He then adds that a spirit called *rak* or *ark* is prepared from the juice, and also a wine called *sheo*.

Bashahr Grapes.

According to Hoffmeister (*Travels*, 1848, 377-8) there appears to have existed a large trade in carrying fresh grapes from Bashahr to Simla. This traffic can hardly be said to exist to-day, though the exports of raisins may be considerable and, moreover, capable of infinite development. The available information regarding the Kanáwar industry is, however, both meagre and contradictory. But with a community of cultivators possessed of an ancient tradition and centuries of experience as vine-growers, much might be expected were viticulture organised on more scientific principles, and with sufficient capital and commercial enterprise.

ombay.

Deccan.

Bo bay.—The earliest definite information regarding the cultivation of the vine in the Deccan would appear to be that already briefly alluded to in the paragraph above on history, viz. the passages from Ibn Batuta, Thevenot, Mandelslo and Ovington, etc. Syed Siraj-ul-Hasan (*l.c.* 224) says, "Looking at the present condition of the fruit trade at Poona and Nasik, one realises what treasure lies buried in Aurangabad and its vicinity. These two places send fruit to the value of many lakhs of rupees to the Bombay market. The writer has personally seen thousands of acres of lands under vine cultivation around Nasik. One merchant alone—a Bohra—exports as much as £33,000 worth of fruit. Why should not Aurangabad compete with the other cities on equal terms? The soil is excellent, as proved by the experience of centuries."

Cultivation.

The moist climate of the Konkan is not suitable for vine-growing, but in parts of the Deccan, *e.g.* Ahmadvagar, Aurangabad, Poona, and especially Nasik, grapes of fair quality are grown for the Bombay market. The vines are usually trained on live posts cut from *Erythrina indica*, a tree known in the vernacular as the *pángara*. The account of cultivation given by Woodrow, which has been already referred to, has special application to Bombay, and should be consulted in this connection. More recently P. S. Kanetkar, Superintendent, Empress Gardens, Poona, gives a full account of viticulture in Poona and the Deccan (*Ind. Plant. and Gard.*, April 21 and 28, 1906). He names five distinct varieties which are cultivated there, viz. *abi* or *bhokri*, *fakdi* or *fakiri*, *habshi* or *kali*, *golkali* and *sahebi*. The field selected "has a kind of garden soil that is neither black clay nor light red (*murrum*), but is a mixture of these, and contains a fair proportion of lime." In the hot weather it is ploughed four or five times and during the rains is left fallow, or *Crotalaria juncea* (*tag*) is

Varieties.

Green Manure.

Transplanting.

grown and ploughed in as a green manure in September. The young vines are reared in nursery beds and then transplanted. The season for transplanting the vine stocks is the month of January. The stock is prepared from the cuttings of the October prunings. "The cuttings, about a foot long, with four eyes or buds upon them, are chosen from ripe wood and are planted in beds, the soil of which is manured with ashes or well rotted farm-yard manure." They are put down in twos, and by January throw shoots about 6 to 9 inches long and become fit for planting out. Previous to planting out the young vines, the field is ploughed along and across, the points of intersection of the furrows being 7 feet apart. At the points where the furrows cross, pits are dug, in each of which a basketful of manure is placed. A pair of young vines is then planted in each pit.

The furrows between the pits serve as water-channels, and water is applied immediately after planting. A second and third watering are given at intervals of four and six days, and later the plantation is watered every eight days till June. When the vines are established, *karvi* stakes (*Strobilanthes callosus*) are driven into the ground and two of the healthier shoots tied to them, while the others are cut off. In this way the vines grow till April, during which time half a basketful of farm-yard manure, or preferably *poudrette*, should be given twice to each vine and all side-growth removed. When the vine has grown over 5 feet (towards April), the ends are nipped off. As a consequence, side shoots are thrown out near the top. About three or four of these shoots are kept and all the lower ones are removed." Stronger stakes of the *pangara* (*Erythrina indica*) are now supplied in place of the *karvi*. "The three or four shoots kept at the top of the vine continue growing till October next, when the pruning for the *mitha bar* (sweet crop) becomes due." After pruning, the ground between the rows of vines is ploughed. No water is given till the shoots blossom, and form small fruits. "About four weeks after pruning the blossoms appear and the fruit sets in a short time afterwards." The bunches are ready to be gathered in March, about six weeks after the grapes begin to get soft. "A well-established plantation about ten years old yields about 10 or 12 lb. of grapes per vine." After the fruit is gathered (in March), no water is given for about a month, and in April the hot-weather pruning is done. "At this pruning the spurs or *kalams* which had three or four buds left on them at the cold-weather pruning for giving the fruit-bearing shoots, are shortened and cut back to two buds, from which alone one or more shoots will spring up to bear the sour fruit of the rainy season." After the hot-weather pruning, the land is again ploughed, harrowed, and manure applied. Water is then given and continued weekly till the rains. In October pruning commences again, as already explained. [Cf. *Repts. Dept. Land Rec. and Agri., Bombay.*]

Second Pruning.

Diseases.—Very little is known regarding the diseases of the vine in Western India. Recently, however, Butler (*Agri. Journ. Ind.*, ii, pt. i., 94-5) furnished a brief report on the subject and identified two out of the four diseases mentioned by Mr. Kanetkar. The four diseases are—(1) *kharda rog* (red or brown rust), (2) *buri* (mildew), (3) *khajalya rog* (black rust), and (4) *karpa rog* (drying-up disease). The second and the fourth are well-known diseases of the vine. *Buri* is *Oidium Tuckeri*, one of the most destructive of mildews; while *karpa rog* is *anthracnose* (*Sphaceloma ampelinum*). Both can be controlled if not checked by flowers of sulphur. [Cf. Maxwell-Lefroy, *An Insect attacking Grape-Vine*, in *Agri. Journ. Ind.*, 1907, ii., pt. iii., 292.]

Diseases.

aluchistan and Sind.—One of the many surprises that meet the visitor to Quetta is the profusion and superior quality of the grapes that are offered for sale. On inquiry these are found to be frequently raised in vineyards where there is practically no rainfall and where few or no streams are seen to carry surface water. Underground, however, the people have excavated drains that communicate from one well to another, until a fairly good flow is established from the upper (often rocky regions) to the more fertile lower plains, where vineyards and fruit gardens abound. The system of subterranean drains (or tunnels) has been adopted as a matter of economy, since the great dryness of the surface soil and

Baluchistan and ind.

Underground Drains.

high temperature of the atmosphere would absorb all the water long before it reached the orchards.

Little information exists as to the methods of cultivation or of manufacture of raisins, but Mr. R. Hughes Buller has furnished some interesting particulars regarding the chief varieties of grapes grown in the Quetta-Pishin district. He enumerates some eighteen, but the most widely distributed are known as *haita* and *spín kishmishi*, followed by *kalamakk*, *husaini*, *tor*, *sra kishmishi*, and *tandán*. The rest, he says, are only met with occasionally. *Haita* is a large oval-shaped grape, with hard skin, of a green colour tinged with yellow. It is very lasting and is the grape commonly packed in wool and sold in Indian bazárs. It is obtainable from August to the end of November. In Kandahár *haita* grapes are made into raisins (*dbjosh*) by dipping them in boiling water mixed with lime and carbonate of soda, and then drying in the sun. *Spín kishmishi* is a small green grape, oblong in shape, found in all parts of the district, especially in Quetta and along the Khwája Amrán. It begins to ripen in August and lasts till the end of October. *Kalamakk* is green, oblong, of medium size, larger than *spín kishmishi* and smaller than *haita*. It ripens from September to 15th November. *Husaini* is a soft fruit, distinguished by its loose growth and by the narrowing of each grape in the centre. It grows in Gulistán, Mazarri, Kamálzai, Arambi and Sariáb, begins to ripen in August, and lasts till the end of October. *Tor* is described as an oval grape, dark in colour and fairly sweet. It ripens early, about the middle of July. *Sra kishmishi* is a small grape, light purple in colour, with soft skin. The Kandaháris make raisins from it. It begins to ripen about the 25th of August and lasts to the 15th of October. *Tandán*, the last mentioned, is a large round, green grape of inferior quality. It contains a large quantity of juice which is extracted in Kandahár, boiled and kept for use as a relish. It ripens in September.

Afghan
Baluchistan
Traffic.

Traffic.—The traffic in grapes (preserved in wooden boxes), arranged layer upon layer, with sheets of cotton-wool between, constitutes one of the characteristic features of the so-called Kabul (Afghan) trade of India. The wandering fruit traders carry grapes, raisins, pistacio nuts, almonds, and pomegranates all over India; and, barring the traffic in Kashmir fruit into the Panjáb and of Deccan grapes into Bombay, the Kabuli traders practically supply the grapes and raisins consumed in the whole of the rest of India. The traffic is, therefore, by no means an unimportant one, and the share taken by the Quetta-Pishin district perhaps the most valuable single contribution.

Raisin Industry.

Pedley wrote an interesting paper (*Agri. Ledg.*, 1893, No. 7) on the possibility of a raisin industry being organised in Sind. He contrasted the Fresno district of California with the Schwan Sub-division of Karachi, and came to the conclusion that with its cheap labour Sind might easily do a large trade in this dried fruit.

engal.

engal and Assa .—The annual rainfall of the province is too high for vine cultivation to be of much importance. In the upper divisions of the province, however, *e.g.* in Bihar, where the climate approximates to that of the United Provinces, greater success has been attained than in Bengal proper, and fairly good grapes are often produced, as at Dinapore and Tirhut. [*Cf. Repts. Dept. Land Rec. and Agri.*]

Trade

therefore become an established industry. On the mountains and tablelands, on the other hand, it is grown with complete success. An account of an interesting experiment at present being conducted in Mysore by an Australian (Mr. M. Paul), is given in the *Indian Agriculturist* (Jan. 1, 1907). Mr. Paul appears to consider the Mysore climate an absolutely ideal one for the vine, and he hopes in a few years to place on the Indian market some twenty varieties of the finest grapes grown in Australia, and equal to any produced on the Continent of Europe. The cuttings imported from Australia were kept partly on the Nilgiri hills and partly in a small nursery at Bangalore, but have now to a large extent been planted out, and are said to be doing very well. In a year it is asserted by Mr. Paul, that he will have a good show of grapes; in two years his little Bangalore vineyard will produce some tons. These grapes, he considers, will sell at a few annas a pound, and he declares that they will be equal to grapes sold in London at five or six shillings a pound. [Cf. Cameron, *For. Trees of Mysore and Coorg*, 1894, 74-5; Rice, *Mysore Gaz.*, 1897, i., 83; *Repts. Govt. Bot. Gard., Bangalore.*]

Nurseries.

Grapes.

Uses.—It is chiefly as a fruit that grapes are cultivated on the tableland of India. But they are at the same time largely eaten in a dried state as raisins or currants, and at one time constituted a fairly important article of food with the people of Kanáwar. The industry of drying grapes is not practised, however, to any very great extent anywhere in India. According to Dutt (*Mat. Med. Hind.*, 1900, 138) raisins have for many centuries been employed medicinally by the Hindus, and he adds that they enter into the composition of numerous demulcent and expectorant medicines in use at the present time. The other products manufactured from the grape are wine, brandy and vinegar (see pp. 1109, 1110).

TRADE.—In the internal trade returns, wines are classed along with spirits (see p. 1047). The foreign trade consists chiefly of imports and re-exports. The exports of Indian produce are quite unimportant, and when compared with the immense population, the imports also are remarkably small. The following table shows the foreign imports of wines of all sorts for the five years 1902-7 :—

Trade.

Imports of Wine.

—	1902-3.	1903-4.	1904-5.	1905-6.	1906-7.	
	Rs.	Rs.	Rs.	Rs.	Rs.	Gals.
Champagne	10,07,620	8,07,144	7,84,015	9,66,182	7,57,812	28,216
Claret ..	2,91,766	2,54,248	1,99,156	2,03,961	1,66,300	44,013
Port ..	7,61,932	7,30,754	7,52,877	8,00,934	7,79,522	95,610
Sherry ..	1,89,657	1,76,279	1,67,478	1,82,307	1,68,006	22,196
Other Sorts	7,50,956	7,59,522	7,15,456	8,21,963	7,68,188	139,307
Total ..	30,01,931	27,27,947	26,18,982	29,75,347	26,39,828	329,342
					= £175,988	

From these figures it will be noted that the imports do not show much tendency to increase. The chief supplying countries and the shares taken by the various provinces may be exemplified by the following analysis of the trade of 1906-7. Of the total quantity (329,342 gallons) imported in

From the United Kingdom.

that year, 150,899 gallons came from the United Kingdom; 99,587 from France; 15,982 from Italy; 11,672 from Belgium; 11,782 from Germany. The quantities from other countries were comparatively insignificant. The shares received by the various provinces (in gallons) were as follows:—Bombay, 105,200; Bengal, 99,308; Madras, 52,360; Sind, 38,230; Burma, 33,968. The shares (in gallons) taken by the chief importing countries in the different sorts of wine may be similarly exemplified by the figures for 1906-7:—CHAMPAGNE—United Kingdom, 13,292; Belgium, 7,819; France, 6,638. CLARET—France, 27,353; United Kingdom, 8,084. PORT—United Kingdom, 77,080; Germany, 7,544. SHERRY—United Kingdom, 18,023. OTHER SORTS—France, 63,416; United Kingdom, 34,420; Italy, 11,418; Spain, 7,022, etc.

309-12.

WITHANIA, *Pauc.*; *Fl. Br. Ind.*, iv., 239-40; Gamble, *Man. Ind. Timbs.*, 1902, 508; SOLANACEÆ. A genus of shrubs, two of which are natives of India.

W. coagulans, *Dunal*. The Cheesemaker or Indian Rennet, *akri*, *panir*, *ashvagandā*, *spin bajja*, *shāpiang*, *khamazora*, *kākanaj*, *amukkura*, *pennēru-gadda*, etc. A small herb common in the Panjāb, Sind, Afghanistan and Baluchistan.

Vegetable
Rennet.

The fruit, both fresh and dried, is used medicinally, but is chiefly important as possessing the property of coagulating milk, and is used for that purpose instead of rennet in Sind, North-West India, Afghanistan and Baluchistan. This property was first noticed and made known by Stocks in 1849 (*Journ. As. Soc. Bomb.*, 56). Mr. S. Lea published an account (*Proc. Roy. Soc.*, 1883, xxxvi., 55-8) of experiments made on the seeds for the purpose of ascertaining whether they contained a definite ferment with the properties of ordinary rennet. The seeds were subjected for 24 hours to the action of various solvents which were then added to milk. A 5-per-cent. solution of common salt in water was found most effective in extracting the ferment, which rapidly curdles milk. In summing up, Lea states that the results of the experiments proved "that the seeds of *Withania* can be used as an adequate and successful substitute for animal rennet." [*Cf. Pharmacog. Ind.*, ii., 569-72; *Agri. Ledg.*, 1893, No. 17, 114; 1895, No. 5, 64-6; *Kew Bull.*, 1903, 27-8.]

W. so nifera, *Dunal*; *Prain, Beng. Plants*, 1903, ii., 750. The *panir*, *asgandh*, *ashvagandhā*, *kūtilal*, *tillī*, *ghodā*, *amukkura*, *pennēru-gadda*, etc. An erect shrub found throughout the drier parts of India; frequent in the west and in Hindustan, rare in Bengal.

Medicine.

Leaves, seeds and root are used in Native MEDICINE, being reputed to have diuretic and narcotic properties. The root, however, according to Dymock (*Mat. Med. W. Ind.*, 1885, 643) "has universally been confounded with a root met with under the same names in the bazārs, but which bears no resemblance to the root of *W. somnifera*." The *asgand* of the shops is the tuber of a convolvulus, which, though much smaller and different in habit, does not appear to differ botanically from *Ipomœa digitata* (p. 686). In Bombay the seeds of this species are employed to coagulate milk in the same way as those of the former, already detailed, and both plants accordingly often bear the same vernacular names.

It yields a GUM, known as *dhaura* or *dhau-ka-gond* of Harauti and Mewar, which is said to resemble gum-tragacanth. The most important part of the plant is, however, the flowers. They appear from February to April, when they are gathered and dried. Throughout India these are employed as a DYE either to produce a colour by themselves or as an adjunct or mordant chiefly with *āl* (*Morinda citrifolia*). Prof. Hummel found them to contain 20·6 per cent. tannic acid and they have long been used as a TAN to a small extent, though for this purpose the flowers have been neglected in favour of the leaves. MEDICINALLY they are employed as an astringent. In the Central Provinces they are said to be eaten as FOOD, and in Bengal are utilised in the preparation of a cooling drink. The wood is used only for FUEL. The plant is a common ornamental shrub in gardens, being easily propagated by cuttings or seed.

Wool.

The chapter devoted to **Live tock** has dealt so very fully with the wild and domesticated goats and sheep of India (pp. 743-9) that there practically remains only the task of reviewing in this place the trade in raw wool and of furnishing a brief summary of the Indian woollen manufactures. But though many of the sheep of India produce fleeces of hair rather than of wool, still fairly good wool is obtained here and there, as, for example, from the black-headed sheep of Coimbatore, the woolly sheep of Mysore, and the sheep found in large tracts of the Deccan, Rajputana, the Panjáb, the United Provinces and Bihar (Patna sheep).

Indian
Supply.

istory.—Wool was known to the very earliest of the classic writers of India, and by the injunctions of the *Institutes of Manu* it is assigned as the material of the sacrificial thread of the Vaisya. In the *Rig Veda*, moreover, there are hymns to P han, the god of the shepherds, which make mention of the bleaching and spinning of wool. Wool is regarded as ceremonially pure, and can accordingly be worn while eating or even performing religious functions. With the Vaishnavas the *sradh* observance should, in fact, be performed only when clad in woollen

History.

Traditions and
Customs.

garments. With most castes the bridegroom attends the wedding service with a woollen charm tied around the waist. Brahma created fire, woollen cloth, the Brahman, and the *kása* grass (see p. 930). From these and such-like references, we are justified in assuming a vast antiquity for the Indian knowledge of wool, as also the arts of spinning and weaving it.

But even with the Muhammadans, the knowledge in wool is no less extensive than with the Hindus. Frequent mention of it occurs in the Arabic and Persian classics. Ali, Fatima, Hasan and Husain are spoken of as the children of the blanket. But in Asia the very earliest woollen garments were produced by plaiting, much after the fashion of grass-mats, and there would seem reason for believing that the property of felting wool was discovered before the art of spinning it. When viewed under the microscope, the individual fibres of wool are seen to be coated with minute scales, and the fibres are, moreover, curly and elastic. To these physical properties are to a large extent due the felting of wool, as the fibres, on being shrunk, get intertwined and bound together. But the wool of sheep reared in tropical countries is less scaly, less curly and more rigid than that of temperate countries, and becomes, in fact, hardly separable from the hair of goats. Hence it follows (to some extent at least) that the knowledge in wool and the position of the woollen industries of India become less and less evident as the approach is made toward the warm moist regions of the tropics or descent is made from the hills toward the plains. It is thus highly probable that the knowledge in wool came to India through the Aryan invaders (who doubtless were largely shepherds), and even to-day wool takes a very subordinate position in the art crafts of India proper, owing doubtless to its unsuitability as a material of clothing under the climatic conditions that prevail for the greater part of the year.

During the early years of the British rule in India much attention was paid to wool, more especially shawl-wool (*pashm*) of the Panjáb, Kashmir and Tibet. The papers written by Webb, Raper, Moorcroft and Hearsay, and later by Smythe, Hutton, Hodgson, Conolly, Cooper, etc., may be specially mentioned as the outcome. But long prior to these, many travellers make mention of wool. Thus, for example, Fryer (*New Acc. E. Ind. and Pers.* (ed. 1698), 224) tells us that the English Company's trade was in his day small from Persia but that they carried a few drugs, Carmania wool, etc. This is, therefore, one of the earliest references by a European to the Kirmani wool, which for many years past has constituted so very important an item in the imports of raw wool drawn by India to its looms.

Characteristics of the Fibre and Trade Classification.—The nature and value of the fibre depends first upon the breed of animal from which obtained; next, the climate, soil and herbage of the country in which reared; and lastly, the method and care with which the fleece has been removed from the animal and sent to market. But it is well known that with every precaution observed, departures and irregularities occur. From the standpoint of buying and selling wool, its merit turns on softness, soundness, fulness and freeness. The individual hairs may vary in length, thickness, and number of scales to the inch very greatly, even within the most carefully selected breed, and moreover they are different on the various parts of the body or during the various seasons of the year, and may even be irregular side by side on the same animal. Mr. N. Burgess, for example, gives the measurement of one hair in a sample of Saxon wool $\frac{1}{17\frac{1}{2}}$ of an inch, while another lying by its side measured $\frac{1}{17\frac{1}{2}}$ of an inch. But to compare with these, he records hair of Southdown with a measurement of $\frac{1}{23\frac{1}{2}}$ of an inch and another $\frac{1}{24\frac{1}{2}}$, the coarsest fibre being $\frac{1}{28}$ of an inch.

As with cotton, so with wool, the merit of the fibre is generally expressed by lengths to which it can be spun. 32's would be the lowest and 80's the highest average yarn. That is to say, in the former 32 hanks of 560 yards each could be spun from the pound of wool, and so 80's would mean that the wool was so fine that one pound could be spun into 80 hanks of the length mentioned, or 44,800 yards. But if the wool be harsh and devoid of elasticity, while in length of staple it may be suited for a certain count, a much lower yarn may actually be possible. Much, therefore, depends upon the condition or texture of the fleece.

As mentioned above, the under-fleece of the Tibetan goats yields the finest of all Indian wools—*pashm*. This is used for the most expensive and artistic purposes in the Indian woollen industries, more especially the shawls and *chadars* presently to be described. It is imported across the land frontier and almost exclusively through Kashmir. Waddell (*Lhasa and Its Mysteries*, 1905, 476-7).

affords some interesting particulars of the *pashm* of Southern and Eastern Tibet. He remarks that the Kashmiris have a monopoly of the trade in Upper Tibet, whence they export it all by way of Rampur on the Sutlej, Kashmir and Ladakh, and canvass for it chiefly in the tracts adjoining there. "In Southern Tibet, however, most of this important product, the felted silky underwool, which should amount to hundreds of tons annually, is wasted, as the Tibetans do not know its great value, and do not collect it from either the yak, when shedding its winter coat in spring, or the goats and sheep."

Imported Kirmani wool and the still more inferior *wahat shahi pashm* (from Persia and Afghanistan), after being treated in a special manner, is extensively employed as a substitute for or in admixture with Tibetan *pashm* in the production of much of the *pashmina* of modern commerce. A more recent and even more pernicious practice is the use of foreign, mostly English, woollen yarns in the fabrication of Indian textiles, for which both the colours and the quality of the yarn are unsuited.

Adulteration.

Indian Wool.—The best wool is that of the Panjáb and Frontier Province, of which perhaps Hissar would take the foremost place, but Ferozpur, Lahore, Jhang, Shahpur, Peshawar, Dera Ismail Khan, Amritsar, Multan, Rawalpindi and Jhelum each produce wool in fair quantity and quality. In the United Provinces the most useful wool comes from the Himalayan tracts—Garhwal, Almora, and Naini Tal—while the important districts in the plains are those of Agra and Mirzapur. A large drain is, however, made on the Panjáb, Rajputana and Sind, and also on foreign countries, to meet the manufactures of these provinces. The best-known local wools of Western India are the black Deccan and Khandesh and the white wools of Sind, Gujarat, and Kathiawar. Sind and Baluchistan wools are exported from Karachi, along with the fine wool obtained from Bikanir. The rearing of sheep in the Central Provinces is fairly important, especially in Jabbalpur, Nagpur, Chanda, Wardha and Raipur. In Rajputana and Central India, Bikanir, Jodhpur, Jaipur and Ajmir produce wool, and that of Bikanir is much prized all over India, especially for carpet-weaving. In Southern India the wools of Bellary, Karnul, Coimbatore and Mysore are well known; but the sheep of most other districts of Madras, like those of Bengal, yield hair rather than wool.

Prices.—In an official report from the Director of Land Records and Agriculture in the United Provinces, the following occurs regarding prices. The price depends upon the purity of the wool, but $2\frac{1}{2}$ seers per rupee may be assumed as a fair average. Bikanir wool (white) fetches from under Rs. 20 to over Rs. 35 per maund, according to fineness and freedom from burrs. Goats' hair costs 10 to 12 seers per rupee and camels' hair 5 seers per rupee.

Price.

INDIAN WOOLLEN MANUFACTURE.

Mr. J. E. O'Connor (*Rev. Trade Ind.*, 1893, 51) made the somewhat significant comment: "The trade is as yet quite unimportant and is likely to remain so for a long time to come, unless the Indian mills are able to find markets in Asia for coarse blankets and horse-clothing, the only descriptions of goods for which there would be a fair demand in the regions we could hope to supply and the only kinds we could manufacture with profit to compete outside India with European goods." In 1895, however, the imports from Great Britain had fallen off by $9\frac{1}{2}$ per cent., while those from Germany had increased sixfold, from France threefold, and from Austria twofold. It had thus almost immediately been demonstrated that the attractively got up cheap shoddy and mixed woollen goods of the Continent of Europe (more especially of Germany) were not only ousting the superior manufactures of England, but had undermined the ground which

the Indian mills were believed capable of holding. In Calcutta, for example, there has existed for many years past a large demand for coolie blankets and shawls, and this has recently been entirely usurped by cheap foreign supply. It is hardly to be wondered at, therefore, that the pioneer woollen mills of India, such as the Cawnpore Woollen Mills Co., Ltd., should have been driven to turn their attention almost exclusively to the production of high-class goods of pure wool in direct competition with the British supply, since their woollen blankets could no longer compete with the cheap low-grade foreign articles. Similarly it has been realised that there was a more profitable market open to the Indian mills in the production of ordinary average quality and even high-class woollen goods than in contracts with the Army Clothing Department of India. Thus it may be said that recent years have witnessed a complete revolution, and a wholesome one, since the date when the original Dhariwal Woollen Mills Company was established, almost exclusively, it might be said, to meet official contracts.

The Dhariwal and Cawnpore Mills may be regarded as favourably placed to tap the supplies of India's finest wools, such as those of Kangra, Simla, Garhwal, Kumaon and Nepal, the South-East Panjab (Shahpur, Dera Ismail Khan, etc.) and South-Western Afghanistan. In some cases these wools have to be carried by road for 200 to 300 miles before they reach the nearest railway station. This is the chief drawback to the Indian mills—the long road transit and consequent heavy charges.

Mills and Woollen Manufactures of India.—In 1876 the Cawnpore Woollen Mills were established, and ten years later (1886) there were four woollen mills in India with a combined capital of Rs. 18,00,000. These gave employment to 1,372 persons, had 242 looms and 5,420 spindles under use. They produced goods to the extent of 798,062 lb., valued at Rs. 5,27,420. Still a decade later (1896) there were 6 mills at work in India with a capital of Rs. 32,50,000, and these gave employment to 3,017 persons, had 530 looms, 18,658 spindles, and produced 2,345,570 lb. of goods, valued at Rs. 24,96,751. During 1904 there were 6 mills with a capital of Rs. 46,25,000, employing 3,468 persons, 737 looms and 25,931 spindles, with a production of 3,508,700 lb. valued at Rs. 36,74,678. That is a record of thirty years' progression of which India has no cause to be ashamed, yet it should be viewed as giving but a foretaste of still greater advancements.

It may perhaps suffice to complete this reference to the Indian power-loom woollen mills to repeat that, as a rule, they concern themselves with the growing demand for goods on a European pattern and style, such as serges, broadcloths, flannels, tweeds, blankets, travelling rugs, etc. They have also given attention to the production of worsted, knitting yarns, Berlin wool, as also knitted goods of all kinds, such as socks, cardigans, jackets, jerseys, caps, gloves, etc., etc. They use pure wool: for the lower grade goods, Indian wool, and for the higher, the finer imported wools, either alone or mixed with Indian. They do not attempt the imitation of Indian special textiles, nor have they as yet engaged in any branch of the European carpet industry.

Indigenous Woollen Industry.—But the official returns of mills take cognisance only of factories that each employ not less than 25 persons and keep these at work mainly, if not exclusively, on the production of woollen goods. Scattered all over India, however, more especially in

the upper provinces, there are small hand-loom workshops in woollen manufactures, and these each employ only one or two hands. In the aggregate they are important, though out of the large number that exist, recognition is made officially of only some 10 or 12, because, though not woollen mills in the strict sense, they are weaving establishments that employ annually from 4,500 to close on 6,000 hands. These larger wool-weaving indigenous establishments are all located within the Panjáb and are concerned for the most part in the production of shawls, *chadars* (see next page), *pashmina*, *jamawar* (or patterned *alwans*), *pattu*, etc., etc. But here and there throughout India there is a fairly large industry in Oriental carpet-weaving (see *Carpets and Ru s*, 272-5) and in felted rugs (*namdas*), and this does not appear to be included in the official returns above indicated. But if the study of the Indian woollen industries be extended so as to include the production of mixed fabrics, that is to say those in which wool constitutes but one, and perhaps the least important ingredient, an extensive assemblage of textiles would be thereby embraced, such as the *himrus*, *mashrus*, *ghattas* and the like. These are mostly made of silk and cotton mixed, but occasionally of wool and silk combined. The name *mashru* (*i.e.* permitted textile) gives the key apparently to the explanation of the richly varied assemblage of fabrics so designated. Pure silk was forbidden to be worn by Muhammadans except on special occasions, and thus the weavers conceived of numerous methods by which an admixture, perhaps of but a small amount, of silk might be thrown on the surface of a woollen or cotton textile to give it the rich effect of being constructed almost entirely of the more expensive and luxurious material. The word *himru* literally means a textile intended to be worn in the cold season. It is woven of cotton so treated as to give it the effect of wool, and is usually brocaded with silk. Occasionally such textiles are made entirely of silk, and are, strictly speaking, *amrus*, but when, in place of cotton, wool is used, they are commonly designated *jamawars*. These are pieces of a fixed length, such as would be required for the preparation of a *choga* or coat, or suitable for a lady's dress. They are simply brocaded woollen goods with the pattern either in very fine *pashm* or in silk, or they may be in cotton, with *pashm* or silk ornamentations. In the *jamawars* of Kashmir, the end pieces are woven straight on, but in Amritsar and Ludhiana they are sewn on. A large percentage of the Kashmiris settled in British India have abandoned the shawl trade and concentrated their attention exclusively on the production of plain *pashmina* or of *jamawars*. They found a lucrative field in the larger towns, especially where these possess a fair percentage of Muhammadans, such as Lucknow, Hyderabad, etc., and in time the weavers adapted themselves to the requirements of their markets and produced *himrus* and other brocaded textiles in which wool was largely replaced by cotton or silk. Within recent years a soft form of wool has been imported into India (and in increasing quantities) originally from Kirman in Persia, more recently from Australia and Afghanistan. So also by special treatment soft staple can be produced from almost any wool. These special wools are worked up alone or in admixture with *pashm* in the production of *pashmina*, a textile imitated in Europe by a fabric known as "Kashmir," which, needless to say, is not made in Kashmir nor in India, any more than a tithe of *pashmina* sold in India and exported to Europe and America is made of *pashm*. [*Cf. Imp. Gaz.*, 1907, iii., 212-8.]

"Kashmir"
a Trade Name.

Shawls and Chadders.—Some years ago the Indian supply set the fashion of wearing these special articles and gave the name shawl (*shal*) to Europe. These textiles are woven of the finest wool (usually the under-fleece of the Tibetan goat), known as *pashm*, an extremely fine hair (which in Europe is called shawl-wool, the textile being *pashmina*). The Rampur *chadar* is usually white or of some plain colour. It is woven of a woollen (*pashm*) warp and a specially prepared silk, sometimes even cotton weft, though occasionally the weft also is of *pashm*. In manufacture, *chadders* are twilled or damasked, but they may be embroidered in the *shal*-stitch fashion, and may even be possessed of narrow ornate borders or be embroidered in pale-coloured or white silk. A large proportion of the soft shawls sold in India to-day as Rampur *chadders*, and which are often carried away by visitors in good faith as being genuine, are made in Europe and sent to India on purpose to meet the demand that exists for these goods.

Much has been written on the Kashmir shawls. Perhaps the earliest account of any note is that given in the *Ain-i-Akbari*, 1590 (Blochmann, transl., 91-2). "His Majesty encourages, in every possible way, the manufacture of shawls in Kashmir. In Lahore also there are more than a thousand workshops." Bernier, who travelled in India in 1656-8, gives some interesting particulars regarding the Kashmir shawls and the woollen manufactures of the Panjáb generally (*Travels*, in Constable, *Or. Misc.*, 1891, 402-5). Great pains, he says, have been taken to manufacture shawls similar to those of Kashmir, in Patna, Agra and Lahore, but, notwithstanding every possible care, they never have the delicate texture and softness of the Kashmir article. Vigne (*Travels in Kashmir*, 1842, ii., 125) affords many useful facts, but Moorcroft (*Travels*, ii., 164-217) produced what might be described as a full technical report of the materials used, methods of fabrication, and trade in Kashmir shawls during the period of his special studies. Lawrence (*Valley of Kashmir*, 1895, 375) carries the story down to the present position of the craft—a tradition, a memory of the past, a degraded industry starved through the loss of the European demand. Dr. A. Mitra, in a pamphlet on the *Arts and Industries of Kashmir State*, says the time was when 60,000 persons were employed in shawl-weaving and brought into the State fifty lakhs of rupees a year. Now, instead of prosperity, the people are sunk in the most abject poverty. [*Cf. Ind Art at Delhi in 1903*, 338-65.]

Kashmir shawls are classified according to size, shape or purpose for which made, *e.g.* plaids, shawls, handkerchiefs, table-covers, curtains, scarves, etc., but it may be said there are two chief modes employed in their artistic ornamentation—(a) *tili* or *kanikar* (patterns elaborated on the loom), and (b) *amlikar* (patterns worked by the needle). The one is woven, the other embroidered, but curiously enough and contrary to what might have been anticipated, the needle (or hand-work) is less expensive and at the same time less artistic than that produced by the loom. A sort of intermediate condition, however, also exists in which the imperfections and shortcomings of cheap loom-work are removed, or made up for by subsequent needle embroidery. But the loom commonly used is hardly more than a few inches in diameter. Strips (braids) or patches are thus woven, then pieced together with the necessary pieces of *pashmina* cloth to form the shawl. The unions are next cleverly obliterated by needlework that can hardly be distinguished from the loom-work. The ground material is usually the finest and purest *pashm*, and

the field (*matan*) may be of one piece (when the shawl is called a *khali-matan*) or consist of four squares of differently coloured *pashmina* (when it is described as a *char-baghan*). If in the centre is placed a medallion of flowers, the shawl is spoken of as a *chand* (moon), and if it has only corner flowers, it is a *kunj*. Lastly, when one end has a deeper band of embroidery than the other, and both ends are much broader than the side strips, the shawl is spoken of as a *shahpasand* or *palledar*.

The chief centres of the Kashmir shawl manufacture to-day are Kashmir, Amritsar, Sialkot, Ludhiana, Gurdaspur and Lahore. The returns given below of the exports of Indian woollen goods afford the only indication available of the extent of the traffic. But for centuries past expensive Kashmir shawls have been much sought after by the princes and nobles of India. The possession of one or more of priceless value was an admitted mark of nobility, and accordingly such shawls were treasured and handed down from generation to generation. Some of the finest known examples of Kashmir shawls are, accordingly, those belonging to the older families. It was perhaps an unfortunate circumstance when the French nobility sought out these expensive garments.

French traders visited Kashmir to purchase their annual supplies and year by year dictated the changes in style which they deemed necessary to meet the ever changing fashions of Paris. An incalculable injury to the art conceptions of the Kashmir people was a necessary consequence of this new trade, and when the Franco-Prussian war put a complete check on the demand, the Kashmir weavers who had become dependent on their French customers were ruined. Meantime Paisley had imitated completely and successfully the Kashmir shawls, and at a price far below what the hand-weavers could accept. Although these imitation shawls had the severity of all power-loom fabrics, they reproduced every detail of the originals and were marvellously woven and extremely beautiful and delicate in texture, so much so that by many they were preferred to the more clumsy though more artistic shawls of Kashmir. The cheapening process soon, however, effected its own ruin. Paisley shawls became so common as to cease to be popular. The demand terminated and the Paisley new industry had to be abandoned, its expensive and ingenious machinery sold as old iron, and its weavers converted into sewing-thread spinners, just as the bulk of the Kashmir shawl-weavers had to become either carpet-weavers or agriculturists. But Paisley has recovered from the loss of its shawl-weaving industry: Kashmir has not. And this is ever the story of art and industrial instinct. The latter lives by conquest, the former dies by contest. [Cf. Andrew Blair, *The Paisley Shawl*, 1906.]

INDIAN TRADE IN RAW WOOL.

Prof. Clapham of Leeds, in an address to the Yorkshire Association for Promoting Commercial Education, gave some striking facts regarding the wool trade of Great Britain. In 1840 the imports from Australia were 40,000 bales; in 1850, 140,000 bales; in 1860, 200,000 bales; and in 1870, 500,000 bales of wool. If by "bales" was meant "sacks" of 364 lb., the imports mentioned for the last year would have been 182,000,000 lb., or just one-half the amount recorded thirty years later.

Up to the opening of the Suez Canal, London was the world's chief emporium for wool, but the establishment of steam shipping and of cable communication, when taken in conjunction with the quick route through the Canal, had the natural effect of bringing the sellers in Australia into

New Route. direct touch with the buyers in Europe, and hence London lost its supremacy in the traffic. In modern returns of the British trade, wool is dealt with under the following headings :—(1) Alpaca, Vicuna and Llama ; (2) Goats' Wool or Hair, Mohair (Angora goats' hair) ; and (3) Sheep or Lambs' Wool. Of the last mentioned, the following statement for the past five years may be given : the countries that supply 10 million pounds and over being alone mentioned and the last three figures omitted as a matter of convenience :—

British Supply.

State ent of Wool Supplies into Great Britain (omitting last three figures).

India's Contribution.

It will thus be seen that the supply of wool drained from British India, when compared with that from Australia and New Zealand, is unimportant. From the Indian point of view, however, it is very considerable, since it represents an amount that might with great advantage have been worked up locally and been thus employed to contest the import traffic in foreign manufactured woollen goods.

Raw Wool.

RAW WOOL.—Little or no information can be furnished as to the total production of wool in India. According to the *Agricultural Statistics*, there were estimated to have been in India during 1905-6, 18,029,181 sheep and 25,172,701 goats. It has further been ascertained that a yield of one seer (2 lb.) of wool per annum would fairly represent the yield of each plains sheep, and something like three seers that of the hills. But it may be added that the returns just mentioned ignore the sheep and goats of the alpine tracts, more especially those across the frontier, from which a large portion of the finest wool of India is derived. And moreover, in the tropical portions of the plains, the sheep yield very little true wool : in fact their fleeces are so poor that they are often not even clipped, the animals being reared purely and simply as sources of mutton. On the other hand, many of the goats yield hair of such a quality that it may be used for some of the purposes for which wool is employed, if indeed goats' hair be not sometimes mixed with wool. And, of course, the under-fleece of the Tibetan goat constitutes the *pashm* or wool, of which repeated mention has to be made in this article. It thus seems safe to assume that one seer per sheep, on the herds actually registered, might be ac-

Yield.

Inferior.

Tibetan Supply.

cepted as fairly representing the annual supply of wool in India, or say 36,058,362 lb. But that estimate may be checked by reference to various records of actual transactions :—

Trans-frontier Traffic.—The imports of wool into India for the latest years of official returns were—1902-3, 92,990 cwt., valued at Rs. 23,91,242 ; 1903-4, 97,125 cwt., valued at Rs. 27,10,041 ; 1904-5, 105,954 cwt., valued at Rs. 30,89,138 ; 1905-6, 141,771 cwt., valued at Rs. 42,45,286 ; and in 1906-7, 171,783 cwt., valued at Rs. 57,86,817. The chief countries that contribute wool to India are South-Western Afghanistan, which in the last-mentioned year gave 105,686 cwt., and Tibet, 34,869 cwt., while the supply from Khelat came to 13,071 cwt. To allow of comparison with other returns, the total imports may be expressed in pounds, viz. 19,239,696. The growing importance of the Trans-frontier wool traffic is one of the most encouraging aspects of the modern trade.

The exports of wool across the frontier are unimportant, and consist chiefly of foreign wool sent to Southern and Western Afghanistan and to Kashmir—the total exports in 1906-7 came to 92,960 lb.

Internal Traffic—Rail and River.—The totals carried during the past six years have been as follows :—1901-2, 197,341 cwt. ; 1902-3, 249,797 cwt. ; 1903-4, 284,680 cwt. ; 1904-5, 359,700 cwt. ; 1905-6, 354,725 cwt. ; and 1906-7, 383,102 cwt. If the last figure be expressed in pounds to allow of ready comparison, we learn that 42,907,424 lb. were distributed by the railways during the year in question. Of that amount 19,239,696 lb. would doubtless correspond with the supply received across the land frontier from foreign countries, thus leaving a balance of 23,667,728 lb. as derived from the sheep of India proper—a figure that, on estimated production, would leave a balance to meet purely local or homestead requirements of 12,390,634 lb.

In an official report of the Department of Land Records and Agriculture in the United Provinces, it is estimated that the local production in these provinces for the year under review (1896-7) may have been something like 2,624,000 lb. The balance available for local consumption (chiefly at the Cawnpore Mills), after adjusting imports and exports on local production, would have been 2,333,556 lb. This view would be in accord with the returns for rail and river traffic, and is perhaps a fairly representative statement of one of the chief provinces in the wool trade of India.

Foreign Exports.—The following were the total exports from India to all foreign countries during the past six years :—1901-2, 19,592,620 lb., valued at Rs. 79,38,259 ; 1902-3, 27,892,898 lb., valued at Rs. 1,16,53,204 ; 1903-4, 33,234,775 lb., valued at Rs. 1,37,73,957 ; 1904-5, 38,571,968 lb., valued at Rs. 1,89,16,747 ; 1905-6, 42,514,498 lb., valued at Rs. 2,11,47,283 ; and in 1906-7, 45,909,898 lb., valued at Rs. 2,42,65,349. Last year's exports thus show an expansion of 8 per cent. in quantity and 14.73 per cent. in total value on the figures of the year preceding, and of 134 per cent. quantity and 205 per cent. in value on the exports of 1901-2. At the same time they maintain a continuous record of progression for the sixth year in succession. Of the total exports in 1906-7, Great Britain took 43,184,135 lb., the United States coming next with 1,578,903 lb. Another significant feature is the rise of the Karachi traffic. In 1901-2 the share taken by that port came to 6½ million pounds, but in 1906-7 it stood at 18½ million pounds. Karachi is to-day about co-equal in im-

portance with Bombay in the export of wool, the two ports between them having taken close on 33 million pounds out of the 45 millions exported in 1906-7. An inspection of the railborne traffic reveals the interesting fact that while the Bombay portion of the exports is drawn from the Bombay Presidency (Rajputana and Central India mainly), that of Karachi is drained from the Panjáb and Sind.

I ports.

Foreign I ports.—The demand for foreign raw wool may be accepted as contributing toward the higher class woollen goods, both hand- and power-loom, though in the former case the foreign wool appears to be largely employed as an adulterant or even a substitute for the more expensive *pashm*. In 1896-7 the imports were returned at 4,725,899 lb., valued at Rs. 14,02,284; in 1898-9 they were 3,283,905 lb.; in 1900-1, 2,871,319 lb.; in 1902-3, 2,756,071 lb.; in 1904-5, 2,117,734 lb.; in 1905-6, 2,908,036 lb., valued at Rs. 9,18,395; and in 1906-7, 2,451,237 lb., valued at Rs. 8,64,505. Practically the whole of these imports are drawn from Persia, with smaller quantities from Mekran and Sonmiáni, and are imported into Bombay and Karachi, a fair portion being thence carried by rail to the Panjáb and the United Provinces. The traffic by sea would seem to have improved steadily up to 1896-7, since which date it might be described as having declined. In 1876-7 the imports of raw wool were valued at Rs. 5,32,116; fifteen years later (1890-1) they stood at Rs. 11,56,154, and attained their maximum five years later still (1896-7), but have ever since almost steadily declined. Against this shrinking demand, however, for foreign wools (brought by sea) has to be placed the expansion of the Trans-frontier traffic already dealt with, especially that across the north-western frontier, which may be regarded as bringing Kirmani wools to India by land routes, to some extent doubtless an expression of increased railway facilities within India itself. [*Cf. Kermanshah Wool, in Dipl. and Cons. Rept., 1903-4, ii., No. 3189, 25-7.*]

anufac-
tures.

Imports.

MANUFACTURED WOOL.—I ports.—The encouraging conception of the Indian woollen industries receives a somewhat severe set-back by an inspection of the foreign traffic. It is not possible to give the returns in pounds, since most of the articles are sold by number or by the yard. The value may, however, be accepted as a sufficiently satisfactory standard. In 1896-7 the IMPORTS of woollen manufactures were valued at Rs. 1,69,24,447; in 1898-9 at Rs. 1,52,37,310; 1900-1 at Rs. 2,11,25,756; 1902-3 at Rs. 1,40,59,122; 1904-5 at Rs. 3,07,64,281; 1905-6 at Rs. 2,42,51,878; and in 1906-7, Rs. 2,05,21,666. Thus in the past eleven years the imports of manufactured wool have expanded from a valuation of £1,128,296 in 1898-9 to £1,368,111 in 1906-7, but if the study be carried still further back, the expansion becomes more marked. In 1876-7 the imports of woollen goods came to only £541,101, whereas the highest record during the past thirty years was in 1904-5, when the supply drawn from abroad by sea was valued at £2,050,952. The Indian mills are thus seen to be securing but a small portion of India's demand for European manufactured woollen goods. But by way of contrast, it may be here mentioned that the exports of Indian woollen goods (mostly Oriental carpets and shawls) rarely exceed £120,000.

Shawls and
Carpets.

Piece Goods.

Turning now to the nature of the imports and countries of supply, the chief item is "piece goods." Out of the total of Rs. 2,05,21,666, the share taken by piece goods alone came to Rs. 1,39,52,624. Of that amount the United Kingdom supplied Rs. 1,03,31,105 and Germany Rs. 26,76,231.

Fully half these imports are consigned to Bombay, one-third to Calcutta, and the balance to Burma, Sind and Madras. Following the "piece goods" come "shawls." During the five years ending 1906-7 these have manifested an average valuation of Rs. 33,07,815 (or, say, £220,521). They come chiefly from Germany, from which the average annual amount consigned to India for the five years ending 1906-7 showed a valuation of £159,324, while from Great Britain the quinquennial average came only to £42,658. What is, however, far more significant, the supply from the United Kingdom contracted from a valuation of Rs. 14,57,354 in 1901-2 to Rs. 81,272 in 1906-7, while from Germany it expanded from Rs. 14,74,562 in 1901-2 to Rs. 46,86,246 in 1904-5, and contracted to Rs. 24,35,951 in 1905-6 and to Rs. 13,04,494 in 1906-7. The shawl traffic is almost entirely with Calcutta, and is very largely the expression of the demand made by the coolies employed in the tea industry for shawls and blankets, so that Germany has not only driven the Indian mills, but the British as well, out of this particular market.

Shawls.

Coolie Traffic.

The imports of woollen carpets and rugs into India have for some years past manifested a continuous expansion. In 1896-7 these were valued at Rs. 4,67,836, and during the past six years the traffic has been as follows:—1901-2, Rs. 8,49,168; 1902-3, Rs. 5,76,304; 1903-4, Rs. 8,96,738; 1904-5, Rs. 13,98,640; 1905-6, Rs. 14,47,131; and in 1906-7, Rs. 10,56,679. During the last-mentioned year carpets and rugs to the value of Rs. 7,30,496 came from the United Kingdom, Rs. 2,04,540 from France, and Rs. 72,219 from Germany. It is only necessary to add (in view of the activity of the Indian woollen mills) that the imports of hosiery came in 1906-7 to Rs. 8,05,614, of which Rs. 6,97,490 worth came from the United Kingdom, two-thirds being taken by Bengal and Bombay and the remaining third by Burma, Sind and Madras.

Carpets.

Hosiery.

Exports.—The total value of the exports of woollen goods came, on the average of the returns for the five years ending 1906-7, to a valuation of Rs. 23,78,835, but the figures as they stand would seem to indicate a shrinkage, the year 1905-6 showing the lowest valuation of the series. But taking 1906-7, the total exports came to Rs. 22,92,838, of which Rs. 16,04,573 represented the portion taken by the United Kingdom, and this is followed by the United States with Rs. 4,03,973; China with Rs. 33,390; and Germany with Rs. 31,699. Thus while Germany supplies India with a yearly increasing quantity of inferior woollen goods, she takes in return practically none of India's manufactures of wool. But it may be added that the exports from India to the United Kingdom, the United States and Germany just mentioned, are almost entirely Oriental carpets and rugs. The exports in shawls are made mainly to the Straits Settlements, and the exports in piece-goods (possibly for the most part Native-made *pashmina*) go to the United Kingdom, Ceylon, Hongkong, the United States, China and Japan.

Exports.

W I G TIA, Br.; Fl. Br. Ind., iii., 652-4; Gamble Man. Ind. Timbs., 1902, 486-7; Cooke, Fl. Pres. Bomb., ii., pt. i., 136-8; Brandis, Ind. Trees, 1906, 461-2; APOCYNACEÆ. A genus of shrubs or small trees of which about six species are found in India, the following being those of economic importance:—

netoria, R. Br.; *indarjav, hyamaraka, khirni, dudhi, kálakado, pála, veypalé, tedlapál, amkudu, kodmurki*, etc. A small deciduous tree of "the

15-

Peninsula of India, common in the Deccan and Karnatak and the Bombay Presidency, extending north to Rajputana and Banda, in deciduous forest; also in Burma" (Gamble).

Rubber.

It yields a crude RUBBER, which was found to give the following analysis:—water, gum, etc., 25·8 per cent.; resin, 45·8; caoutchouc, 28·4. [Cf. *Ind. For.*, 1903, xxix., 406–7.] The seeds are said to be used as an adjunct to other materials in dyeing, while from remote times the Natives of Southern India have employed the leaves as a source of blue dye or indigo. The root-bark and seeds, though of no value medicinally, have been the cause of considerable confusion in the literature of Indian *Materia Medica*, being frequently mistaken for and used to adulterate those of *Holarrhena antidysenterica* (see p. 640). The Wood is of good quality for carving and turning, and is fairly extensively used for both these purposes. It is said to resemble ivory in colour and texture, and according to Rice (*Mysore Gaz.*, 1897, i., 81) is employed for making the celebrated Chena-patna toys and for wooden idols. [Cf. *Pharmacog. Ind.*, ii., 397–8; Cameron, *For. Trees Mysore and Coorg*, 1894, 186–7; *Pharm. Journ.*, 1901, lxxvii., 690.]

Indigo.

Timber.

Idols.

W. to *entosia*, Roem. & Schult.; Prain, *Beng. American.

A tall annual grass, according to De Candolle originally native of New Granada, but now cultivated almost throughout the world. The cultivated races are very numerous and show great power of adaptation to local environment, so much so that efforts to introduce American forms into India have generally resulted in degeneration towards the existing (now often called indigenous) forms. There seems no doubt that maize came to India from America, and was possibly brought thence direct by the Portuguese. But it appears to have been cultivated in India for at least a hundred years before forms were evolved, for each tract of country, of sufficient merit to justify extensive production. When, however, India had obtained its own special forms, maize moved rapidly over the whole continent, assuming tropical conditions in some parts, temperate and even arctic in others.

History.

istory.—The admirable account of the origin of this plant furnished by De Candolle (*Orig. Cult. Plants*, 387–97) leaves little that can be here added of any material value. Maize was unquestionably introduced into India just about the time of the advent of the East India Company, and the first mention in their *Proceedings*, of what may possibly be this grain, occurs in a letter of date October 1621, addressed to the Surat agent by Capt. John Weddell, in which he suggests that a "warehouse be hired at Swally for the temporary housing of the 'chanderouze'" (*khandarus* = an Arabic name for maize) (Foster, *Engl. Factories Ind.*, 1906, 296). It is, however, highly likely the *khandarus* in question was *judr* and

not maize—that Arabic name being now applied to both grains. Baber (*Memoirs* (portion written 1520-9)) makes no mention of having seen maize on his arrival in India, though he carefully describes all the animals and plants new to him. Moreover, the early European travellers in India, including the botanists Rheede and Rumphius, are silent regarding this cereal. Abul Fazl (*Ain-i-Akbari*—the *Adminstr. Rept.* of the Emperor Akbar for 1590 A.D.), in his long list of grains and pulses grown in India during the 16th century, does not include maize, but he remarks under *kéura* (Pandanus, see p. 777) that its leaves are like those of maize (Blochmann, transl., 83). The word “maize” is of course furnished by the translator, and must be an incorrect rendering. It is interesting to note, however, that Mendoza (*Hist. China*, 1585) mentions amongst the plants observed by him “the plant called maize, which constitutes the principal food of the Indians in Mexico” (Bretschneider, *Hist. Europ. Bot. Disc. in China*, 1898, 10). In the 18th century Burmann published his *Thesaurus Zeylanicus* and his *Flora Indica*, but in neither does he allude to *Zea*. Hove, who at the close of the 18th century (1787) visited Bombay in order to study its cotton, wrote a report full of information on all the crops seen by him, but does not mention Indian-corn. But it would perhaps be unsafe to assume that, although the pine-apple was fully known in the 16th century, so extremely valuable a plant as the maize had not reached India until after the date when Rumphius wrote his great work (*Herb. Amb.*, 1750), which to some extent figures and describes the plants of India. If we can accept the passage above indicated from Foster as satisfactorily establishing the existence of the grain in India, it must have been an article of commerce nearly a century previous to the date at which Rumphius wrote.

Not seen by Baber.

Mentioned in China.

The most general vernacular name in India for this corn is *makkai* (Mecca corn), which may be regarded as manifesting the association of the grain with the Muhammadan rulers of India and at the same time accepted as strongly suggestive of the Portuguese influence at the court of the Mughal. The displacement accomplished by the new cereal, or rather its appropriation of names formerly given to certain forms of *Sorghum*, may be viewed denoting the innate propensity of Asiatics to contrast all new ideas with previous conceptions. The origin of its other most general name, *bhuta*, is more obscure, but is probably derived from *bhukta* or *bhutta* to eat. Both names are clearly modern, however, and do not occur in any classic works of even the most recent date. So very little progress had, however, been made with maize cultivation that Roxburgh wrote, about the beginning of the 19th century, that Indian-corn was “cultivated in various parts of India in gardens, and only as a delicacy; but not anywhere on the continent of India, so far I can learn, as an extensive crop.” Buchanan-Hamilton (*Kingdom of Nepal*, 1819, 284, 312), while dealing with the ancient State of Yumla (its capital Chhina-chin) says that they had maize. In a further page, he remarks of Kangra—“The poor live much on maize.” Very shortly after the appearance of Roxburgh’s *Flora Indica*, however, Graham (*Cat. Pl. Bombay*, 1839, 240) wrote of Western India that maize was “commonly cultivated.” Dalzell and Gibson (*Fl. Bomb.*, 1861 (suppl.), 100), some thirty years later (1861), said that it was “extensively grown in the early part of the rains, especially near large towns.” These authors also add—“The grain is seldom used in India as a flour.” But as illustrative of the extremely local character of the information often furnished by Indian writers, it may be added that Stewart (in 1862) wrote of Bijnour that “much of the maize was ground into flour and made into bread, although very much less is here used in this way than in the Panjab.” It is thus very probable that in Upper India (a region, comparatively speaking, unknown to Roxburgh) maize was much more extensively grown at the beginning of the century than might be inferred from Roxburgh’s words. At the present day it would be more nearly correct, at any rate, to speak of maize as of equal value to the people of India collectively with wheat, instead of its being grown purely as a garden “delicacy.” It is a field crop upon which at least the bulk of the aboriginal tribes of the hilly tracts of India are very largely dependent for subsistence. Thus its diffusion over India, during the present century, might almost be said to be one of the most powerful arguments against the statement often made that the Natives of India are so very conservative that they can scarcely be induced to change their time-honoured customs, even when these can be shown to be inimical to their best interests. So completely has India now appropriated the *makkai* that few of the village fathers would be found willing to admit that it had not always been with them, as it is now, a staple article of diet.

CULTIVATION.—Though grown practically all over India, the area of maize cultivation as a ripe grain may be said to be the central tableland, the northern extremity of the plains, and the Himalayan slopes and river valleys up to an altitude of 9,000 feet above the sea. On the lower or Gangetic plain it is grown chiefly as a green vegetable. In the vicinity of large towns the sale of the unripe cob is so remunerative that by peculiar systems of cultivation and selection, special forms have been matured that could scarcely be eaten in the condition of ripe grain. On the other hand, within the region where maize is grown for its ripe grain, it is hardly possible to procure green cobs as a vegetable. But adaptation to local conditions is perhaps more strikingly seen in the fact that in many parts of India there are forms of maize that require six months to mature, others not more than three months. In some parts of the country, indeed, both kinds may be seen growing separately or as mixed crops. Further it may be added that where the transition of the seasons into *kharif* and *rabi* crops allows of tropical cultivation during the former and temperate during the latter, two widely different forms of maize may be found. In the greater part of the plains of India, maize is a *kharif* crop, but *rabi* maize is by no means unusual, *i.e.* maize sown in autumn and reaped in spring along with wheat and barley.

Area.—According to the *Agricultural Statistics*, the area under the crop in British India for the six years 1900–1 to 1905–6 averaged 6,083,484 acres, and in the last year, 1905–6, was 5,790,543 acres. In the Native States the area during a similar period averaged 269,017 acres, and in 1905–6 was 221,687, giving a total for all India in that year of 6,012,230 acres. Bengal had the largest average area during the period in question, viz. about 2 million acres; followed by Agra with about 1½ million; the Panjáb, from 1 to 1½ million; Oudh, ½ to ¾ million; the North-West Frontier, ¼ million; while the Central Provinces and Bombay had 130 to 160 thousand acres under the crop. But it should be here recorded that the above areas do not include production as a green vegetable, an important admission, since nearly every peasant grows a few plants near his home-stand, which of necessity escape registration in agricultural statistics.

Diseases.—Barclay described a species of Rust found by him on Indian-corn (*Agri. Ledg.*, 1895, No. 20, 284–5); a species of Smut (*Ustilago*) has also been recorded (*l.c.* 278). More recently Maxwell-Lefroy (*Agri. Journ. Ind.*, 1906, i., pt. ii., 97–113; also *Mem. Dept. Agri. Ind.*, 1907, i., No. 2) discusses the Moth-borer of the sugar-cane, maize and sorghum.

Bengal.—The area in 1905–6 was 1,825,400 acres and the yield, according to the *Season and Crop Report*, 448,670 tons. The largest areas were Patna Division with 820,500 acres, Bhagalpur with 657,800 acres, and Chota Nagpur with 307,800 acres. The yield per acre varies considerably, but the provincial average for the years 1901–2 (*Agricultural Statistics*) shows so little difference between the returns for unirrigated as compared with irrigated, that the latter may be disregarded. The yield for unirrigated land comes to 1,522 lb. to the acre. The districts that show the highest yield are Santal Parganas (2,739 lb.) and Manbhum (2,447 lb.). Mukerji (*Handbook Ind. Agri.*, 1901, 249–53) states that “5 to 8 maunds of grain per acre is considered a fair yield, but 30 to 40 maunds are sometimes obtained.”

Maize cultivation may be said to manifest three phases :—(1) the home-stand cultivation in Lower Bengal, to produce green cobs; (2) the cultiva-

PROVINCIAL RESULTS

A AY
Cultivation

tion as a staple food-grain on the hilly tracts, such as Chota Nagpur; and (3) the cultivation in Bihar, which differs in no essential from that in the greater part of the United Provinces. The method of cultivation described by Basu (*Agri. Lohardaga*, 1890, pt. i., 65-6) may be considered typical for the hilly parts of the Lower Provinces. Two varieties are there distinguished, a dull yellow and a red. It requires a rich soil and is usually grown for two to three successive seasons on the same plot, followed by some cold-weather crop like mustard. In June-July the land is ploughed and the seed sown broadcast, 4 to 5 seers per acre, and buried by a light ploughing. The field is then weeded and hoed two or three times from June to August, and the cobs ripen from the middle of August to the middle of September. If they are to be roasted and eaten, they are picked a fortnight before ripening (Basu). According to Mukerji, "the value of a 5 to 8 maunds' crop is only about Rs. 10. An acre (if ravages of jackals are prevented) may produce 20,000 green cobs. If these are sold at an average price of 8 cobs per pice, the produce of one acre may come up to Rs. 35 to Rs. 40." [Cf. Grierson, *Bihar Peasant Life*, 1885, 223-4; Banerji, *Agri. Cuttack*, 1893, 77; Roy, *Crops of Beng.*, 1906, 51-4; *Sabpur Exper. Farm Repts.*]

Varieties.
Soils.
Seasons.
Profit.

Assa.—The area in 1905-6 was 1,300 acres, chiefly in Nowgong and Sylhet, but it is nowhere grown to any appreciable extent. In Cachar, Darrang and Sibsagar it is said to be grown in small patches, chiefly by foreigners. In the Khasia, Jaintia, Garo and Lushai hills, B. C. Allen states that "it is either grown in garden ground or is sown in the potato fields at the time when the tubers are earthed up. It is usually sown in April and May and ripens in August and September. The maize fields are well hoed and treated with manure" (*Assam Dist. Gaz.*, 1906, x., 72-3).

Assam.
Season.

United Provinces.—The area in Agra in 1905-6 was 1,374,267 acres, and in Oudh 796,976 acres. The average outturn for the provinces for the years 1897-1902 is stated to have been 950 lb. per acre. The acreage in the chief districts during 1905-6 was as follows:—*Agra*—Meerut, 121,307; Districts Balandshahr, 120,481; Gorakhpur, 115,587; Aligarh, 97,905; Jaunpur, 88,216; Saharanpur, 83,054; Bareilly, 78,936; Etah, 65,745, etc. In *Oudh*—Bahraich, 255,914; Gonda, 206,471; Kheri, 96,487, etc.

U. Prov.

Maize is one of the crops which has for many years been systematically studied at the Cawnpore Experiment Station, and much valuable information relative to the varieties grown, the manures used and the seasons of sowing and reaping, will be obtained by referring to the voluminous annual reports. The account given by Duthie and Fuller (*l.c.* 22) may, however, be considered typical of the ordinary Native methods. It is a *kharif* crop sown, as a rule, when the rains break, and harvested at the end of August. If the cobs are to be sold as vegetables they are pulled while green; otherwise they are left till the leafy envelopes surrounding them are dry and shrivelled. Generally it is cultivated alone, but sometimes "cucumbers are grown between the lines. It is not uncommon, too, to mix a certain proportion of the lesser millets (*kakuni* and *mandwa*) and a little pulse (*urd*). The average outturn for the provinces, Duthie and Fuller estimate at 10 maunds for unirrigated and 14 maunds for irrigated maize.

Kharif.
Outturn.

With regard to the Cawnpore experiments, an interesting summary of these is given by Mr. Subbiah, Principal, Cawnpore Agricultural School (*Dept. Land Rec. and Agri. Bull.*, 1901, No. 16), to which the reader is referred. He there states that "since 1895 outturns ranging from 30 to

35 maunds of grain have been repeatedly obtained on a number of plots, and occasionally as much as 40 maunds and more." Regarding varieties, he remarks that "about eighteen American and the two common North Indian varieties have been tried at the station with a view to test their merits as regards hardihood, productiveness and suitability to the climate of North India. The results of these trials showed that American varieties could be grown without any difficulty the same year the seed was imported; that one or two Americans might excel the Indians in productiveness; but that, taking everything into consideration, the two country varieties are the best for our present local conditions; that much better practical results could be immediately achieved by improving these two varieties by a careful selection of seed, etc.; and that with the light-yellow country variety as improved at Cawnpore the best results that the North Indian climate and soil would admit of might be attained within a few years." Subbiah further states that to secure yields approaching those obtained at Cawnpore, the agents at the cultivator's disposal are (a) regular spacing of each individual plant; (b) selection of seed or using Cawnpore maize seed; (c) two diggings between the crop in addition to the usual weeding and earthing; (d) one or two waterings during breaks in the rains that occur in most years; (e) liberal manuring; (f) either deep ploughing or digging with *phaora* before sowing."

Cost. By the ordinary method of cultivation he estimates the cost per acre to be Rs. 13-13 and the normal produce 13 maunds, worth Rs. 22-12, giving a profit of Rs. 8-15; by the Cawnpore method, the cost is Rs. 31-12, outturn 35 maunds worth Rs. 61-4, giving a profit of Rs. 29-8.

[Cf. Wright, *Mem. on Agri. Cawnpore*, 1877; Duthie and Fuller, *Field and Garden Crops*, l.c. 21-4, t. v.; Leather, *Exper. on Wheat and Maize at Cawnpore*, Dept. Land Rec. and Agri. U. Prov. Bull., 1900, No. 9; Nevill, *Dist. Gaz. U. Prov.*, 1903-6 (many passages); *Repts. Bot. Gard. Saharanpur; Cawnpore Exper. Farm Repts.*]

C. Prov. and Berar. *Central Provinces and Berar.*—The area in 1905-6 was 134,329 acres in the Central Provinces, and 2,445 acres in Berar. The chief districts in the former are Chhindwara, Mandla, Betul, Bilaspur and Jabbalpur; in the latter, Wun and Buldana. Practically no information is available regarding the cultivation of the crop. The *Nagpur Experimental Farm Reports* deal only with the efforts to acclimatise American races and races from other parts of India.

Panjáb and North-West Frontier. *Panjáb and North-West Frontier.*—The area in 1905-6 was 896,241 acres in the Panjáb and 341,862 acres in the North-West Frontier. In the Panjáb the area would appear to be declining. For the five years ending 1901-2 the average outturn for the Panjáb is stated to have been 1,133 lb. per acre irrigated and 841 lb. unirrigated; in the North-West, 1,665 lb. irrigated and 583 lb. unirrigated. From returns submitted from various districts it was calculated in the *Dictionary* that an average yield for the province would be about 886 lb., or 10½ maunds per acre. In the Panjáb the districts with largest acreage were Kangra, 140,585; Hoshiarpur, 118,853; Jalandhar, 83,204; Gurdaspur, 59,808; Sialkot, 54,482; Ludhiana, 54,228; Ferozpur, 52,627; Ambala, 52,405; Lahore, 42,070; Amritsar, 42,013, etc.; in the North-West—Hazara, 162,699, and Peshawar, 130,002.

In a volume entitled *Selections from the Records of the Financial Commissioner's Office* (1887, No. 36, 780-836), the subject of maize cultivation in the Panjáb was fully discussed. The periods of sowing and reaping vary

greatly. Speaking generally it is a *kharif* crop in the plains, sowing being dependent on the rains taking place, usually from June to August. The crop begins to bear green cobs (from the earliest sowing) in August, and ripe grain (from later sowings) in September, October or even November. On the hills the sowings are generally much earlier, and the higher reaches are earlier than the lower. In Hazara, Kullu and Simla, for example, early sowings are in April and May. While these are the general principles, remarkable variations occur in some districts, such as Rawalpindi, where there are two widely different crops that correspond very nearly to the *kharif* and *rabi* seasons. [Cf. Lawrence, *Valley of Kashmir*, 1895, 336-7; *Settl. Repts. and Dist. Gaz., Panjab and N.-W. Frontier*; *Repts. Govt. Agri.-Hort. Gardens, Lahore.*]

Bo bay and Sind.—The area in 1905-6 was 158,115 acres in Bombay; 1,400 acres in Sind. In Bombay, Panch Mahals claims two-thirds of the total area, 110,950 acres, and in Sind about two-thirds of its total are confined to Karachi. Mollison (*Textbook Ind. Agri.*, iii., 52-3) describes the cultivation in Panch Mahals and the Deccan. In the former, he says, "it is grown either as a rain or late irrigated crop." With sufficient rainfall it does best on the rich brown soils of the district, recently brought under cultivation, but rice land also suits the crop. It is usually grown alone, and requires a soil deeply and carefully tilled. The land is liberally manured, usually in May. "The crop tests of the Presidency show that 10 to 15 lb. per acre of seed is the ordinary rate." It is harvested when dead ripe. "In the Panch Mahals an average crop may be estimated at 1,200 to 1,500 lb. per acre." In the Deccan it is often grown for fodder. "A heavy crop will yield over 20,000 lb. of green fodder per acre." The cost of cultivation Mollison estimates at Rs. 13-6 per acre. [Cf. *Exper. Farm Repts., Bombay.*]

Madras and Mysore.—The area in 1905-6 was 76,377 acres in Madras; 231 acres in Mysore, but this represents a great contraction, the average being about 2,000 acres. The area in Madras also shows a decrease on previous years. The largest acreages were in Guntur, 37,237; Tanjore, 14,059; and Kistna, 12,897. Maize does not appear to be a crop of much importance in South India, and it is better described as a plant of gardens rather than of fields. [Cf. Cox, *Man. N. Arcot*, 1895, i., 269.]

ur a.—There were 94,942 acres under the crop in Upper Burma in 1905-6; 18,003 in Lower Burma. In Upper Burma the chief districts are ordinarily Magwe, Pakókku, Myingyan, Minbu, Yaméthin and Meiktila; and in Lower Burma, Thayetmyo. There is little information available regarding cultivation. It appears to be most frequently grown as a mixed crop. Parlett (*Settl. Rept., Sagaing Dist.*, 1893-1900) states that it is "common all over *kaing* lands, as a rule sown sparsely in among *pegya*." Harvest, he states, is usually completed by April 1, and the cost of cultivation is estimated at Rs. 2-50 per acre. [Cf. *Settl. Oper. Repts.*; *Repts. Dept. Land Rec. and Agri.*]

ECONOMIC AND INDUSTRIAL.—The chief uses of this cereal are as an article of human and cattle food—the stems and leaves being also valued as FODDER. It is mainly in Upper India that the ripe grain is reduced to a flour and made into bread. In some parts of the country it is ground into meal and eaten as porridge, known as *lapsi* or *gathá* in Bengal. But, as already stated, the green cobs are extensively eaten after being roasted or boiled. The ripe grain is also often parched and eaten as a mid-

Flour.	day meal. The preparation known in Bengal as <i>satu</i> is the parched grain reduced to flour, much as in other parts of India <i>satu</i> is the flour of parched grain and barley mixed. The straw of the ripe crop is not of great value as fodder (except for elephants), but reaped in a green state it is very valuable. Both in Europe and America, Indian-corn is largely employed in the production of special articles of food that differ in some cases but little from the ancient <i>satu</i> of India; these bear the names Hominy, Maizena, Polenta, Indian-corn flour, etc.
Indian-corn Flour.	
America.	In the United States it is perhaps but natural that a fuller knowledge and more complete utilisation of maize should have been attained than in India. Next perhaps to cotton, maize is the most valuable crop grown in the States, and the utilisation of its various by-products has given rise to numerous flourishing industries. A full account of these is given by Wiley (<i>U.S. Dept. Agri. (Chemistry), Bull.</i> , 1898, No. 50). The grain is largely employed in the manufacture of STARCH and STARCH SUGAR or glucose, which in the United States is extensively employed in the manufacture of whisky and alcohol (Hanausek, <i>Micro. Tech. Prod.</i> (Winton and Barber, transl.), 1907, 40-1). A sugar is also prepared from the juice of the stems (<i>D.E.P.</i> , vi., pt. iv., 332). Recently the waste material from the manufacture of glucose has been utilised in the production of a RUBBER said to have both the resiliency and wearing power of genuine Para rubber.
Starch or Starch Sugar.	From the germ of the seed is obtained by expression a valuable OIL, used for lighting, lubrication, soap-making, and as a salad oil. Among minor uses it may be mentioned that the pith of the stalk "has been used with the greatest success in the construction of battleships in the American Navy, the compressed blocks being placed between the two walls of armour." The pith is also "easily nitrated into all the various forms of material commonly made from cotton," and is said to have "many advantages over cotton for nitrating purposes, especially in the manufacture of explosives of all kinds, by reason of its more perfect keeping qualities" (Wiley, <i>l.c.</i> 27). Finally the stems, leaves and spathes are used in the manufacture of PAPER which is spoken of as suitable for bank-notes, while the residues from the manufacture of starch, glucose, whisky and alcohol are utilised in the production of a special article of CATTLE-FOOD.
Rubber.	"Formerly it was the custom to employ these waste matters in the moist state, but in most parts of the country this method has been superseded by the method of drying the residues and selling them in the anhydrous condition. In this state they are much more easily transported, the objectionable odours which were the predominant characteristic of the moist foods are removed, and the wholesomeness of the food is in every way promoted" (Wiley, <i>l.c.</i> , 25, 30). Similarly a special preparation of the whole plant, except the root and ear, is discussed by Wiley under the name of "Maize Stover."
Oil.	"As has before been intimated, this fodder is often fed in the coarse state without any preparation whatever. In this condition a very large percentage of it is wasted, the cattle eating little except the blades and perhaps some of the smaller and tenderer parts of the stalk. In the older parts of the country, it is now becoming quite general to have the maize stover finely shredded before being fed. This not only increases the quantity which becomes available for feed, but also leaves the manure in a much better condition for spreading on the field."

Trade.	TRADE. —Unfortunately no information on this nature can be furnished. Jackson (<i>Comm. Bot.</i> 19th Century, 47-8) mentions that the

BRITISH TRADE IN MAIZE

INGI
I I A L
Gin er

imports of Great Britain came to 444,453 cwt. in 1856, and by 1889 had expanded to 36,203,069 cwt. The traffic continued to expand, and in 1899 stood at 66,741,350 cwt., valued at £12,978,025, but in 1903 it declined slightly, to 50,099,328 cwt., valued at £12,465,583; in 1904 to 42,897,880 cwt., valued at £10,247,134; in 1905 to 42,101,210 cwt., valued at £11,034,748; and in 1906 stood at 48,685,200 cwt., valued at £11,972,694. About one-half comes from the Argentine, a little less from the United States, and the balance from Roumania, Canada, Russia and British East Indies, in the order named. The Indian traffic in maize appears under the designation of "other sorts of grain and pulse," but as the foreign exports in these collectively are comparatively unimportant and, moreover, fluctuate extremely, they may be disregarded. In 1904-5 the total exports under this heading came to 1,691,672 cwt., in 1905-6 to 112,042 cwt., and in 1906-7 to 21,226 cwt. The imports of maize taken by Great Britain from India are returned as 206,900 cwt. in 1904; 917,700 cwt. in 1905, and 23,800 cwt. in 1906.

British Traffic.

Argentine Supply.

From India.

The following are the average wholesale prices (minimum and maximum) of maize per 10 maunds in the various provinces of India for 1905:—BENGAL, from Rs. 18·65 in Bhágálpur to Rs. 21·05 in Patna; UNITED PROVINCES, from Rs. 18·12 in Shahjahánpur to Rs. 26·29 in Aligarh; PANTJAB, from Rs. 16·78 in Ferozpur to Rs. 21·58 in Multan.

Ginger.

Habitat.

istory.—Ginger is known to have been cultivated in India and China for many centuries. Its most general Chinese name is *kiang*. Bretschneider tells us that "Confucius was never without ginger when he ate." It is mentioned in the *Li Ki*, among the articles of food there enumerated. Turning to India, the word "ginger" is generally believed to come from the Sanskrit "*sringavera*," through the Arabic "*zanzabil*," and from the same source was doubtless derived the corresponding Greek name "*zingiber*." Knowledge in the tuber seems accordingly, to have reached Europe *viâ* Africa and Arabia, and to have been very ancient in India. Dioscorides describes the country of ginger, and gives the distinctive features of the best kinds. Galen, Paulus Ægineta and other Greek and Roman authors give full details of the medicinal virtues of the drug, and are followed by the Arab medicinal writers, such as Mesua, Serapion, Avicenna, etc. Coming down to more recent times, Marco Polo (13th century)

istory.

China.

India.

Three Kinds.

Indian
Travellers.

(*Travels* (ed. Yule), ii., 312) was familiar with both the fresh and preserved root; he specially mentions Coilum (the modern Quilon) in Malabar as affording the best quality. This appears to have been known to the merchants of the Middle Ages as "Colombino," or "Coilumin," a term that became a little later "Columbine" ginger. Three names that denote countries of supply are constantly mentioned—namely *Belledi*, *Colombino* and *Mecchino*. The *belledi* or *balladi* came from various districts of India, *mecchino* from Mecca, and *colombino* from Quilon. The word *balladi* seems to be an exact equivalent of *desi*, and to mean "country," and ultimately denoted a common or inferior article. Rashiduddin speaks of the exports of "*baladi*" from Gujarat, and Nicolo Conti, who travelled in India in the early part of the 15th century, remarks that in the neighbourhood of Pacamuria and Helly, two cities of the west coast, there "grows ginger, called in the language of the country, *beledi*, *gebeli* and *neli*." Barbosa mentions ginger as exported from Calicut in the beginning of the 16th century. So also Garcia de Orta, who wrote in 1563, and again Linschoten, in 1598, give long, interesting accounts of it. In the following century Terry (1655) says that it grows "almost in every place" in the southern part of the Great Mughal's territory; Mandelslo (1662) that it is found abundantly in Gujarat; and lastly, Tavernier (1676) refers to its prevalence in the kingdom of the Great Mughal. From these and such-like accounts by travellers in India, it may be inferred that ginger was already well known and a trade established in it even in the early Middle Ages. [*Cf. Paulus Egineta* (Adams, transl.), iii., 123; Nicolo Conti, *Ind. in 15th Century* (ed. Major), 6; Vertomannus, *Travels*, 1503, in *Hakl. Voy.*, iv., 577; Barbosa, *Coasts E. Africa and Malabar* (ed. Hakl. Soc.), 220-1; Garcia de Orta, 1563, *Coll.*, xxvi.; also in Ball, *Proc. Roy. Ir. Acad.*, 3rd ser., 1889-91, i., 411; Acosta, *Tract. de las Drogas*, 1578, 259; Linschoten, *Voy. E. Ind.*, 1598 (ed. Hakl. Soc.), ii., 78-80; Pyrrard, *Voy. E. Ind.*, etc. (ed. Hakl. Soc.), ii., 356, etc.; Clusius, *Hist. Exot. Pl.*, 1605, 212; Terry, *Voy. to Ind.*, 1655, 92; Boym, *Fl. Muscovy*, etc., 85; Tavernier, *Trav. in Ind.* (ed. Ball), 1676, ii., 13; Milburn, *Or. Comm.*, 1813, ii., 209.]

Cultiva-
tion.

CULTIVATION.—The plant is cultivated all over the warmer and moister parts of India, up to an elevation of 4,000 to 5,000 feet in the Himálaya. The cultivation is one on which much care and labour are bestowed. The soil must be rich, but neither too heavy nor too light, and the amount of moisture must be carefully regulated. Manure is freely used and weeding carefully and frequently carried out (Nicholls, *Textbook Trop. Agri.*, 1892, 194-6).

en al.

Bengal.—Ginger is said to be largely grown in many parts of the province, but no statistics of area are available. Buchanan-Hamilton (*Stat. Acc. Dinaj.*, 186) gives many interesting particulars as to methods of cultivation, yield, etc. In Rangpur it might be said that ginger and tobacco, taken together, constitute the second most important crop, jute being first and rice third. According to Roy, a fine sandy loam is most suitable, and the crop follows a *kachu* (*Colocasia antiquoru*, p. 398) or a pulse crop. The land is prepared by repeated ploughings from the 15th February to the 15th April, then levelled and water-channels dug along and across the fields. "Well-rotted cow-dung at the rate of 100 maunds per acre is applied at the time of the first ploughing. In August-September the plants are top-dressed with 6 maunds of mustard-cake and 6 maunds of castor-cake per acre." "The rhizomes preserved from the previous year's crop, cut into pieces about 3 inches long, are planted out at the rate of 12 maunds per acre. They are planted in parallel furrows drawn 15 inches apart and about 8 inches apart in the furrow, at right angles to the subsidiary water-channels." The field is frequently hoed and weeded and irrigated twice a month during the cold season if there be no rain. The rhizomes are dug up

Rangpur.

I GI I I AL Cultivation

from October to March. "The average yield is 40 to 60 maunds per acre." [Cf. Sen, *Rept. Agri. Stat. Dacca*, 1889, 41; Banerjee, *Agri. Cuttack*, 1893, 103; Roy, *Crops of Bengal*, 1906, 157-8.]

United Provinces.—Ginger is extensively grown in all hotter valleys in Kumáon. A piece of ground not liable to be flooded is selected and protected from excessive rainfall by trenching round the upper side. The soil is well hoed and manured and the ginger planted in furrows in April. The whole field is then covered with leafy branches kept in place by bamboo or wooden poles. The rhizomes are gathered in February.

Panjab.—As in the United Provinces, ginger cultivation is carried on chiefly in the lower hot valleys of the Himálaya. The rhizomes selected for planting are preserved in heaps covered with cow-dung. The land is ploughed at the end of June or beginning of July, divided into beds, and saturated with water. Leaves are applied as in Kumaon, but a layer of manure is placed over the leaves in addition. After the rains cease, artificial irrigation is necessary from October to January. In January the rhizomes are dug out and removed to another place for a month, after which they are exposed to the sun for a day, and are then fit for use. A *bigha* is stated to require 8 maunds of ginger to plant it, and yields 32 maunds in a good crop.

o bay.—According to the *Season and Crop Report*, there were 596 acres under ginger in 1905-6, chiefly in Thána, Surat, Satára and Kaira. Mollison (*Textbook Ind. Agri.*, iii., 182-6) has recently described fully the methods of cultivation. "It grows to great perfection on the deep, alluvial, sandy loams (*gorádu*) of Kaira and Baroda. The garden land of Surat, in which the crop is important, is somewhat heavier, but of the same general character and consistence. In the Thána district, where the rainfall is heavy, the crop is only grown in the strip of deep, sandy soil which fringes the coast in the Máhim and Bassein Tálukas."

"In Thána, ginger is rotated with betel vines, plantains, and sugar-cane. In Northern Gujarát it is rotated with a number of other garden crops, such as sugar-cane, *surans*, turmeric, onions, garlic, chillies, *brinjals*, cabbages, *methi*, etc. Most of these crops are found in different patches in the same garden in a single year."

"Ginger in Thána is grown alone. In Northern Gujarát, a thick sprinkling of *guvár* is sown with the crop. Yams are planted at the corners of the beds and along the *bándhs* which separate the beds, or, instead of yams, turmeric may be so grown." Mollison then describes in detail the methods pursued in Kaira, for which the reader is referred to the original. Planting the sets takes place in May or early in June before the monsoon breaks, and Mollison estimates that about 77,000 sets are required per acre, varying in weight from about 1,200 lb. to 2,000 lb. The crop is ready for harvest by November or December. "Under favourable conditions, an acre may yield 12,000 lb. of dry cleaned rhizomes. The sun-dried partially cleaned rhizomes are sold by the cultivators to dealers at 40 to 50 lb. per rupee in ordinary seasons. Selected pieces of rhizomes after storage for several months are worth as sets for replanting about 25 lb. per rupee. A crop test which was taken in the Surat district in good garden-land in 1895-6 gave for a mixed crop of ginger and turmeric the following outturn:—ginger, 8,337 b. per acre; turmeric, 3,564 lb. per acre." Mollison estimates the cost of cultivation in Surat at Rs. 183 per acre. In the *Pharmacographia Indica* mention is made of many qualities

THE GINGER PLANT

of ginger. "One variety found in gardens in the Konkan has a darker colour than the ordinary ginger and somewhat of a zedoary flavour; it is known as *kala-ala* or black ginger." [Cf. *Repts. Dept. Land Rec. and Agri., Bombay; Crop Exper., Bombay.*]

Madras.—The best Malabar ginger, spoken of so highly by Linschoten, is said to be the produce of the district of Shernaad to the south of Calicut. The soil is a rich red earth, and cultivation generally commences about the middle of May, after the ground has been thoroughly ploughed and harrowed. At the commencement of the monsoon, beds are formed, and on these, holes are dug and filled with manure. Cuttings of the rhizomes are placed in the holes and the beds covered up with a layer of leaves. A fair supply of rain is necessary, but, as inundation entirely ruins the crop, great care is taken in draining. The rhizomes are dug up about November. There are no statistics available relative to area or outturn.

PREPARATION AND USES.—The rhizomes are dug out with a small hand-pick and then consigned to a dealer, who sells them as fresh ginger or converts them into *sunth* (dried ginger). The pieces of rhizomes are known by spice dealers as "races" or "hands." Nicholls (*Textbook Trop. Agri.*, 1892, 196) describes two methods of drying the rhizomes after they have been dug out, viz. they may be plunged into boiling water for some minutes and then dried in the sun, or they may be scraped with a knife till the black outer skin is removed and then sun-dried. The former is known as "unscraped," "coated," or "black" ginger, the latter as "scraped," "uncoated," and "white." Uncoated Cochin ginger is reputed to be the best kind produced in India. Mollison thus describes the preparation in Surat: "The first operation in *sunth*-making is to soak the partially cleaned rhizomes in water. This with rubbing cleans the rhizomes, and also softens them. The soaking facilitates the removal of the outer skin. It is scraped off with a shell or broken piece of earthenware. The scraped ginger is now washed and exposed for three or four days to the sun on an ordinary threshing-floor. The ginger is thus bleached and dried. It is now rubbed by hand. The object is not clear. The operation is done carefully, so that the shoots are not broken. The ginger is then bleached in the sun for three or four days, and again hand rubbed. It is now steeped in water for two hours, and exposed on a clean floor to the sun until it gets dry. When dry it is rubbed on a coarse cloth or coarse sacking. This removes any outer skin not previously removed by scraping. The *sunth* is now ready for market. The cost of *sunth*-making is about Rs. 3 per *khandi* of 20 maunds of green ginger."

Ginger has long been known both to Hindu and Muhammadan medicine, and its uses in European MEDICINE are well known. It is sold in almost every bazar throughout India, and is largely employed as a condiment, especially in the preparation of curries. Gildemeister and Hoffmann (*Volatile Oils*, 1900, 313-5) give particulars of the ginger OIL trade. The rhizome is also pickled and an excellent preserve made by cooking the fresh young rhizomes in syrup. The manufacture of ginger-beer and ginger-ale forms a large portion of the mineral water trade in England and the States. Besides being used as a spice, confection or medicine, ginger is thus used in gingerade, ginger-ale, ginger-beer, ginger-brandy, ginger-wine, gingerbread, ginger lozenges and ginger essence. Soluble essences are required in the manufacture of most of the liquors, etc., in which ginger becomes an important ingredient. The traffic in Jamaica unbleached ginger is very considerable. [Cf. *Pharmacog. Ind.*, iii., 420-5; Waring, *Bazar Med. Ind.*, 1897, 69-70; Parry, *Chem. of Essential Oils and Artif. Perfumes*, 1899, 136-7; Dhargal Ker, *Notes on Therap. of Indig. Veg. Drugs.*, 1899, 64; Dutt, *Mat. Med. Hind.*, 1900, 253-5; Blyth, *Foods Compos. and Anal.*, 1903, 25; *Journ. Agri.-Hort. Soc. Ind.*, 1902, xii., n.s., 85-7; Ghosh, *Treat. Mat. Med.*, 1904, 656; Leach, *Food Inspect. and Anal.*, 1905, 345-50.]

TRADE.—The Indian internal trade in ginger is fairly large and important. During the five years 1901-2 to 1906-7 the total transactions by rail and river averaged 90,639 cwt., amounting in 1906-7 to 86,211 cwt. The largest quantities in that year were exported from EASTERN BENGAL and ASSAM with 20,009 cwt. (almost all to Calcutta),

THE INDIAN JUJUBE

I YP U
JUJU A
ér

followed by BOMBAY PORT, 13,110 cwt. (to Bombay Province, Central Provinces and Berar, Panjáb, United Provinces, Rajputana and Nizam's Territory); PANJÁB, 10,728 cwt. (to Karachi, United Provinces, etc.); MADRAS, 6,648 cwt. (to Madras ports); UNITED PROVINCES, 10,002 cwt. (to the Panjáb and Bengal).

Similarly, by coast the exports in 1905-6 amounted to 2,634,020 lb., valued at Rs. 3,21,160. The great bulk of these coastwise exports went from MADRAS, viz. 1,984,040 lb., and were consigned chiefly to Bombay, viz. 1,902,294 lb. BOMBAY is the only other exporting centre of any importance, from which the exports in the same year amounted to 587,461 lb.

xports.

Turning to the foreign trade, the following have been the quantities EXPORTED for the six years 1901-2 to 1906-7:—1901-2, 5,758,616 lb., valued at Rs. 13,02,323; 1902-3, 7,397,702 lb. and Rs. 16,59,499; 1903-4, 12,061,517 lb. and Rs. 24,91,055; 1904-5, 11,164,019 lb. and Rs. 19,26,784; 1905-6, 9,869,174 lb. and Rs. 12,52,740; and in 1906-7, 5,415,531 lb. and Rs. 9,67,209. Analysing the figures for the last year, we find that from Bombay there were exported 2,314,778 lb., from Madras 2,032,038 lb., and from Bengal 1,068,620 lb. The chief markets were the United Kingdom, which received 1,565,020 lb.; Aden, 1,517,696 lb.; United States, 960,801 lb.; Arabia, 378,544 lb.; Ceylon, 242,373 lb.; and Germany, 219,920 lb. For a similar period the IMPORTS were:—1901-2, 863,837 lb., valued at Rs. 1,68,313; 1902-3, 664,041 lb. and Rs. 1,29,036; 1903-4, 2,104,746 lb. and Rs. 3,41,204; 1904-5, 874,625 lb. and Rs. 1,07,071; 1905-6, 1,089,515 lb. and Rs. 1,35,876; and in 1906-7, 1,026,344 lb. and Rs. 1,70,421. These quantities come almost entirely from Japan and China, which contributed in the last year (1906-7) 875,360 lb. and 117,820 lb. respectively, and go chiefly to Bombay and Bengal, which imported 824,561 lb. and 187,560 lb.

Upper Gang. Plain*, 1903, 163). The grafted ber is called *poyndi*. Burkill (*MS. Notes on Tour in Rohtak*) remarks on four kinds extensively grown, viz. *umari*, *nasuk*, *pendi* and *kutia*. Lisboa observes of *bordi* that it is one of the commonest fruit trees of the villages of Western India. A moderate-sized deciduous tree, "distinctly wild in the forests of the Siwaliks and Sub-Himalayan tracts of the Panjáb and United Provinces, and also in the Deccan and in Upper Burma and Ceylon in dry forests. Elsewhere mostly cultivated or run wild" (Gamble).

Indian
Jujube.

Habitat.

The bark is said to be used for TANNING in Northern India, Bombay, Madras and Burma. In Chota Nagpur it is similarly employed, but along with the fruit. Occasionally it is thrown into indigo-vats to aid in precipitating the fecula. Hooper (*Agri. Ledg.*, 1902, No. 1, 20) states that a sample of bark from Madra gave 4.1 per cent. of tannin, and a sample of thick root examined at Dehra Dun gave 2.6 per cent., while some thin roots afforded 9.3 per cent. Most parts of the tree are employed in Native MEDICINE. The fruit of the wild *ber*, which ripe in the cold weather—the cultivated one almost in any season (Collett, *Fl. Sim.*, 1902, 90)—resembles the crab-apple in flavour and appearance, and is much eaten, well as that of most species, by the poorer classes; Fruit Eaten.

Tan.

Medicine.

Fruit Eaten.

	in fact, in times of scarcity these fruits are specially prized. By cultivation it is greatly improved both in size and flavour, and there is great variety among the cultivated forms. According to Marshall Woodrow, "the best are elliptical, two inches in length by one in thickness and are propagated by inarching or budding on seedlings of the common sort." The unripe fruit is pickled; the ripe pulp is dried, mixed with salt and tamarinds, to form a condiment or is made into chutnies. The kernels are also eaten, and the leaves constitute a useful FODDER for cattle and goats. The WOOD is hard and reddish in colour, weighing on an average 48 lb. per cubic foot. It is largely employed in ordinary constructive work and has been recommended for furniture. It is also said to make excellent CHARCOAL. The lac insect is commonly reared on the tree (see <i>Tachardia lacca</i> , p. 1057), and it is one of the food-plants of the <i>tasar</i> silkworm (see p. 1005), while in Assam the <i>eri</i> silkworm is sometimes fed on it as well (see <i>Silk</i> , p. 1012). [Cf. Baber, <i>Memoirs</i> , 1519 (Leyden and Erskine, transl.), 326; Garcia de Orta, 1563, <i>Coll.</i> , xxviii.; also in Ball, <i>Proc. Roy. Ir. Fodder.	
Timber.	
Charcoal.	
Co on Jujube.	<i>. vulgaris</i> , Lamk. The Common Jujube, <i>titni-</i> (or <i>phitni-</i>) <i>bér</i> , <i>kandika</i> , <i>singli</i> , <i>bán</i> , <i>bárij</i> , <i>ganyeri</i> , <i>shamor</i> , <i>amlai</i> , <i>relnú</i> , <i>anáb</i> , <i>unnáb</i> , <i>rán-bor</i> , etc. A large shrub or small tree "wild in the Panjab from the Indus to the Ravi; much cultivated in the Panjab, Kashmir, Baluchistan, etc." (Gamble).
Fruit.	The tree is chiefly important on account of its FRUIT, which is very similar to that of <i>Z. Jujuba</i> , being an oval pulpy drupe about the size of a plum. It varies much and can be greatly improved by cultivation and grafting.
Dried.	The dried fruit is the jujube of Arabian and Persian works on <i>Materia Medica</i> , and has long been known as an article of commerce. The Indian market is supplied from China and the Persian Gulf, the Chinese fruit being preferred as it is larger and sweeter. In Europe it is used in the preparation of syrups, confections and lozenges (<i>pate de jujube</i>) taken to allay cough. In order to ascertain the composition and value of these fruits a consignment was sent to London in 1904, and a report was submitted by Dunstan (<i>Imp. Inst.</i> , March 3, 1905). The fruits were chemically examined, but the results showed that they contained no constituents to which definite medicinal qualities could be ascribed. The report further adds that "it was considered possible that confectioners might be able to make use of such materials for the preparation of candied fruit or in some similar way, but the absence of any peculiar flavour and the somewhat mawkish taste of the pulp were considered insuperable difficulties by the firms to whom samples of the fruits were submitted for consideration from this point of view."
Imported.	Specimens of the fruit were also submitted to dealers in cattle-food in the hope that it might be used for mixing with ground pulse and similar products as a sweetening agent. The fruit was considered suitable for this purpose, but experts were of opinion that owing to its bulkiness it could not compete in this direction with similar products such as the carob bean. The report concludes by stating that there appears to be "no immediate prospect of any commercial outlets being formed for these dry fruits, but the inquiry will be continued, and it is possible that some new development in trade may suggest a method for their utilisation in the future." [Cf. Bentham, <i>Rev. of Targioni-Tozzetti</i> , in <i>Journ. Hort. Soc.</i> , 1855, ix., 165; De Candolle, <i>l.c.</i> 194; <i>Pharmacog. INDEX

This work being alphabetical, a complete index to the subjects dealt with becomes superfluous. In the pages that follow, therefore, will be found all the vernacular and other names mentioned in the text, as also cross references to subjects that might otherwise have escaped observation. Minor products that find positions in collective articles and do not therefore appear in their alphabetical positions are included in the index. Scientific names of unimportant products, such as species of birds, fish, insects, etc., are not included, except their English and vernacular names. Names of places, persons, books consulted and analytical details have been purposely omitted. It is believed the marginal notes and cross references within the text fully meet these requirements. The citations to the *Dictionary of Economic Products of India* have been uniformly given on the margin as "D.E.P." Vernacular names, as also scientific synonyms (when given), are in italics, English names in ordinary type, and modern scientific names in small capitals.
